4 FAQ 11
4.1 What does GDAL stand for? . . . 11
4.2 What is this OGR stuff? . . . 11
4.3 What does OGR stand for? . . . 11
4.4 What does CPL stand for? . . . 11
4.5 What does VSI stand for? . . . 11
4.6 When was the GDAL project started? . . . 11
4.7 Is GDAL/OGR proprietary software? . . . 11
4.8 What license does GDAL/OGR use? . . . 12
4.9 What operating systems does GDAL-OGR run on? . . . 12
4.10 Is there a graphical user interface to GDAL/OGR? . . . 12
4.10.1 Software using GDAL . . . 12
4.10.1.1 Free and open source . . . 12
4.10.1.2 Proprietary license / Other . . . 14
4.11 What compiler can I use to build GDAL/OGR? . . . 16
4.12 I have a question that's not answered here. Where can I get more information? . . . 16

4.13 How do I add support for a new format? . . . 16
4.14 What about file formats for 3D models? . . . 16
4.15 Is GDAL thread-safe ? . . . 16
4.16 Does GDAL provide a Section 508 information? . . . 16
4.17 How do I cite GDAL ? . . . 16

5 Programs **17**
5.1 "gdal" application . . . 17
5.1.1 General . . . 17
5.1.1.1 Main `gdal` entry point . . . 17
5.1.1.2 Syntax for commands of `gdal` program . . . 19
5.1.1.3 Migration guide to `gdal` command line interface . . . 21
5.1.1.4 Bash completion for `gdal` . . . 25
5.1.1.5 How to use `gdal` CLI algorithms from C . . . 27
5.1.1.6 How to use `gdal` CLI algorithms from C++ . . . 30
5.1.1.7 How to use `gdal` CLI algorithms from Python . . . 31
5.1.1.8 .gdalg files to replay serialized `gdal` commands . . . 35
5.1.2 Commands working with raster or vector inputs . . . 36
5.1.2.1 `gdal info` . . . 36
5.1.2.2 `gdal convert` . . . 64
5.1.2.3 `gdal pipeline` . . . 64
5.1.2.4 `gdal external` . . . 77
5.1.3 Raster commands . . . 79
5.1.3.1 `gdal raster` . . . 79
5.1.3.2 `gdal raster info` . . . 81
5.1.3.3 `gdal raster as-features` . . . 91
5.1.3.4 `gdal raster aspect` . . . 94
5.1.3.5 `gdal raster blend` . . . 97
5.1.3.6 `gdal raster calc` . . . 109
5.1.3.7 `gdal raster clean-collar` . . . 114
5.1.3.8 `gdal raster clip` . . . 116
5.1.3.9 `gdal raster color-map` . . . 121
5.1.3.10 `gdal raster contour` . . . 124
5.1.3.11 `gdal raster compare` . . . 128
5.1.3.12 `gdal raster convert` . . . 130
5.1.3.13 `gdal raster create` . . . 132
5.1.3.14 `gdal raster edit` . . . 136
5.1.3.15 `gdal raster footprint` . . . 141
5.1.3.16 `gdal raster fill-nodata` . . . 146
5.1.3.17 `gdal raster hillshade` . . . 149
5.1.3.18 `gdal raster index` . . . 153
5.1.3.19 `gdal raster materialize` . . . 157
5.1.3.20 `gdal raster mosaic` . . . 159
5.1.3.21 `gdal raster neighbors` . . . 163
5.1.3.22 `gdal raster nodata-to-alpha` . . . 168
5.1.3.23 `gdal raster overview` . . . 170
5.1.3.24 `gdal raster overview add` . . . 170
5.1.3.25 `gdal raster overview delete` . . . 174
5.1.3.26 `gdal raster overview refresh` . . . 175
5.1.3.27 `gdal raster pansharpen` . . . 178
5.1.3.28 `gdal raster pipeline` . . . 181
5.1.3.29 `gdal raster pixel-info` . . . 204
5.1.3.30 `gdal raster polygonize` . . . 211
5.1.3.31 `gdal raster proximity` . . . 214

5.1.3.32 gdal raster pipeline read . . . 217
5.1.3.33 gdal raster reclassify . . . 218
5.1.3.34 gdal raster reproject . . . 222
5.1.3.35 gdal raster resize . . . 229
5.1.3.36 gdal raster rgb-to-palette . . . 231
5.1.3.37 gdal raster roughness . . . 234
5.1.3.38 gdal raster scale . . . 236
5.1.3.39 gdal raster select . . . 240
5.1.3.40 gdal raster set-type . . . 242
5.1.3.41 gdal raster slope . . . 244
5.1.3.42 gdal raster sieve . . . 248
5.1.3.43 gdal raster stack . . . 250
5.1.3.44 gdal raster tile . . . 254
5.1.3.45 gdal raster tpi . . . 261
5.1.3.46 gdal raster tri . . . 263
5.1.3.47 gdal raster unscale . . . 266
5.1.3.48 gdal raster update . . . 268
5.1.3.49 gdal raster viewshed . . . 271
5.1.3.50 gdal raster pipeline write . . . 277
5.1.3.51 gdal raster zonal-stats . . . 278
5.1.4 Vector commands . . . 285
5.1.4.1 gdal vector . . . 285
5.1.4.2 gdal vector buffer . . . 287
5.1.4.3 gdal vector check-coverage . . . 294
5.1.4.4 gdal vector check-geometry . . . 299
5.1.4.5 gdal vector clean-coverage . . . 304
5.1.4.6 gdal vector clip . . . 309
5.1.4.7 gdal vector combine . . . 314
5.1.4.8 gdal vector concat . . . 318
5.1.4.9 gdal vector concave-hull . . . 323
5.1.4.10 gdal vector convert . . . 328
5.1.4.11 gdal vector convex-hull . . . 331
5.1.4.12 gdal vector create . . . 335
5.1.4.13 gdal vector dissolve . . . 339
5.1.4.14 gdal vector edit . . . 342
5.1.4.15 gdal vector filter . . . 346
5.1.4.16 gdal vector info . . . 350
5.1.4.17 gdal vector export-schema . . . 361
5.1.4.18 gdal vector explode-collections . . . 363
5.1.4.19 gdal vector grid . . . 367
5.1.4.20 gdal vector index . . . 375
5.1.4.21 gdal vector layer-algebra . . . 379
5.1.4.22 gdal vector make-point . . . 385
5.1.4.23 gdal vector make-valid . . . 388
5.1.4.24 gdal vector materialize . . . 392
5.1.4.25 gdal vector partition . . . 394
5.1.4.26 gdal vector pipeline . . . 398
5.1.4.27 gdal vector rasterize . . . 421
5.1.4.28 gdal vector pipeline read . . . 426
5.1.4.29 gdal vector rename-layer . . . 427
5.1.4.30 gdal vector reproject . . . 432
5.1.4.31 gdal vector select . . . 436
5.1.4.32 gdal vector segmentize . . . 441
5.1.4.33 gdal vector set-field-type . . . 444

5.1.4.34 gdal vector set-geom-type . . . 448
5.1.4.35 gdal vector sort . . . 453
5.1.4.36 gdal vector simplify . . . 455
5.1.4.37 gdal vector simplify-coverage . . . 460
5.1.4.38 gdal vector sql . . . 464
5.1.4.39 gdal vector swap-xy . . . 469
5.1.4.40 gdal vector update . . . 472
5.1.4.41 gdal vector pipeline write . . . 474
5.1.5 Multidimensional raster commands . . . 477
5.1.5.1 gdal mdim . . . 477
5.1.5.2 gdal mdim info . . . 477
5.1.5.3 gdal mdim convert . . . 482
5.1.5.4 gdal mdim mosaic . . . 485
5.1.6 Dataset management commands . . . 488
5.1.6.1 gdal dataset . . . 488
5.1.6.2 gdal dataset identify . . . 488
5.1.6.3 gdal dataset check . . . 491
5.1.6.4 gdal dataset copy . . . 492
5.1.6.5 gdal dataset rename . . . 493
5.1.6.6 gdal dataset delete . . . 494
5.1.7 Virtual System Interface (VSI) commands . . . 495
5.1.7.1 gdal vsi . . . 495
5.1.7.2 gdal vsi copy . . . 496
5.1.7.3 gdal vsi delete . . . 497
5.1.7.4 gdal vsi list . . . 498
5.1.7.5 gdal vsi move . . . 499
5.1.7.6 gdal vsi sync . . . 500
5.1.7.7 gdal vsi sozip . . . 502
5.1.8 Driver specific commands . . . 507
5.1.8.1 gdal driver cog validate . . . 507
5.1.8.2 gdal driver gpkg repack . . . 508
5.1.8.3 gdal driver gpkg validate . . . 509
5.1.8.4 gdal driver gti create . . . 510
5.1.8.5 gdal driver openfilegdb repack . . . 515
5.1.8.6 gdal driver parquet create-metadata-file . . . 516
5.1.8.7 gdal driver pdf list-layer . . . 517
5.1.8.8 gdal driver zarr add-georeferencing-convention . . . 518
5.2 "Traditional" applications . . . 519
5.2.1 General . . . 519
5.2.1.1 Syntax of arguments of command-line utilities . . . 519
5.2.2 Raster programs . . . 519
5.2.2.1 Common options for raster programs . . . 519
5.2.2.2 gdal-config (Unix) . . . 522
5.2.2.3 gdal2tiles . . . 522
5.2.2.4 gdal2xyz . . . 528
5.2.2.5 gdal_calc . . . 529
5.2.2.6 gdal_contour . . . 534
5.2.2.7 gdal_create . . . 538
5.2.2.8 gdal_edit . . . 540
5.2.2.9 gdal_fillnodata . . . 543
5.2.2.10 gdal_footprint . . . 544
5.2.2.11 gdal_grid . . . 547
5.2.2.12 gdal_merge . . . 554
5.2.2.13 gdal_pansharpen . . . 557

5.2.2.14 gdal_polygonize . . . 559
5.2.2.15 gdal_proximity . . . 561
5.2.2.16 gdal_rasterize . . . 563
5.2.2.17 gdal_retile . . . 566
5.2.2.18 gdal_sieve . . . 569
5.2.2.19 gdal_translate . . . 569
5.2.2.20 gdal_viewshed . . . 577
5.2.2.21 gdaladdo . . . 580
5.2.2.22 gdalattachpct . . . 587
5.2.2.23 gdalbuildvrt . . . 587
5.2.2.24 gdalcompare . . . 592
5.2.2.25 gdaldem . . . 594
5.2.2.26 gdalenhance . . . 602
5.2.2.27 gdalinfo . . . 604
5.2.2.28 gdallocationinfo . . . 614
5.2.2.29 gdalmanage . . . 617
5.2.2.30 gdalmove . . . 619
5.2.2.31 gdalsrsinfo . . . 620
5.2.2.32 gdaltindex . . . 624
5.2.2.33 gdaltransform . . . 629
5.2.2.34 gdalwarp . . . 632
5.2.2.35 nearblack . . . 644
5.2.2.36 pct2rgb . . . 646
5.2.2.37 rgb2pct . . . 647
5.2.3 Multidimensional Raster programs . . . 649
5.2.3.1 gdalmdiminfo . . . 649
5.2.3.2 gdalmdimtranslate . . . 652
5.2.4 Vector programs . . . 655
5.2.4.1 Common options for vector programs . . . 655
5.2.4.2 ogrinfo . . . 656
5.2.4.3 ogr2ogr . . . 665
5.2.4.4 ogrtindex . . . 677
5.2.4.5 ogrlineref . . . 678
5.2.4.6 ogrmerge . . . 681
5.2.4.7 ogr_layer_algebra . . . 684
5.2.5 Geographic network programs . . . 686
5.2.5.1 gnmmanage . . . 686
5.2.5.2 gnmanalyse . . . 688
5.2.6 Other utilities . . . 689
5.2.6.1 sozip . . . 689

6 Raster drivers **693**
6.1 AAIGrid -- Arc/Info ASCII Grid . . . 696
6.1.1 Driver capabilities . . . 697
6.2 ACE2 -- ACE2 . . . 697
6.2.1 Driver capabilities . . . 698
6.3 ADRG -- ADRG/ARC Digitized Raster Graphics (.gen/.thf) . . . 698
6.3.1 Driver capabilities . . . 699
6.4 AIG -- Arc/Info Binary Grid . . . 699
6.4.1 Driver capabilities . . . 699
6.4.1.1 Arc/Info Binary Grid Format . . . 699
6.5 AIRSAR -- AIRSAR Polarimetric Format . . . 710
6.5.1 Driver capabilities . . . 711
6.5.2 See Also . . . 711

6.6 AVIF -- AV1 Image File Format . . . 711
6.6.1 Driver capabilities . . . 712
6.6.2 Color Profile Metadata . . . 712
6.6.3 Georeferencing . . . 712
6.6.4 Creation options . . . 712
6.6.5 See Also . . . 713
6.7 BAG -- Bathymetry Attributed Grid . . . 713
6.7.1 Driver capabilities . . . 713
6.7.2 Open options . . . 714
6.7.3 Variable resolution (VR) grid support . . . 714
6.7.4 Spatial metadata support . . . 716
6.7.5 Tracking list support . . . 716
6.7.6 Creation support . . . 716
6.7.7 Usage examples . . . 717
6.7.8 See Also . . . 719
6.8 BASISU -- Basis Universal . . . 719
6.8.1 Driver capabilities . . . 720
6.8.2 Creation options . . . 720
6.8.3 Build instructions . . . 720
6.9 BMP -- Microsoft Windows Device Independent Bitmap . . . 721
6.9.1 Driver capabilities . . . 721
6.9.2 Creation Options . . . 722
6.9.3 See Also . . . 722
6.10 BSB -- Maptech/NOAA BSB Nautical Chart Format . . . 722
6.10.1 Driver capabilities . . . 722
6.10.2 Metadata . . . 723
6.11 BT -- VTP .bt Binary Terrain Format . . . 723
6.11.1 Driver capabilities . . . 723
6.12 BYN - Natural Resources Canada's Geoid file format (.byn) . . . 724
6.12.1 Driver capabilities . . . 724
6.12.2 Factor . . . 725
6.12.3 See Also . . . 725
6.13 CAD -- AutoCAD DWG raster layer . . . 725
6.13.1 Driver capabilities . . . 725
6.14 CALS -- CALS Type 1 . . . 726
6.14.1 Driver capabilities . . . 726
6.14.2 Metadata . . . 726
6.14.3 Creation issues . . . 727
6.14.4 See Also . . . 727
6.15 CEOS -- CEOS Image . . . 727
6.15.1 Driver capabilities . . . 727
6.16 COASP -- DRDC COASP SAR Processor Raster . . . 727
6.17 COG -- Cloud Optimized GeoTIFF generator . . . 728
6.17.1 Driver capabilities . . . 728
6.17.2 Creation Options . . . 729
6.17.2.1 General creation options . . . 729
6.17.2.2 Reprojection related creation options . . . 733
6.17.3 Update . . . 734
6.17.4 File format details . . . 734
6.17.4.1 High level . . . 734
6.17.4.2 Low level . . . 735
6.17.4.3 Header ghost area . . . 735
6.17.4.4 Tile data leader and trailer . . . 736
6.17.5 Examples . . . 737

6.17.5.1 Example 1: Create a COG with gdalwarp . . . 737
6.17.5.2 Example 2: Create a Web Mercator COG with Google Maps–Compatible Tiling and JPEG Compression . . . 737
6.17.5.3 Example 3: Create a blank GeoTIFF from an existing file . . . 737
6.17.6 See Also . . . 737
6.18 COSAR -- TerraSAR-X Complex SAR Data Product . . . 737
6.18.1 Driver capabilities . . . 738
6.18.2 See Also . . . 738
6.19 CPG -- Convair PolGASP data . . . 738
6.19.1 Driver capabilities . . . 738
6.20 CPHD - Compensated Phase History Data . . . 739
6.20.1 Driver capabilities . . . 739
6.20.2 Open options . . . 739
6.20.3 Multidimensional API support . . . 739
6.20.4 See Also . . . 739
6.21 CTG -- USGS LULC Composite Theme Grid . . . 739
6.21.1 Driver capabilities . . . 740
6.22 DAAS (Airbus DS Intelligence Data As A Service driver) . . . 740
6.22.1 Driver capabilities . . . 741
6.22.2 Dataset name syntax . . . 741
6.22.3 Authentication . . . 741
6.22.4 Configuration options . . . 741
6.22.5 Open options . . . 741
6.23 DDS -- DirectDraw Surface . . . 742
6.23.1 Driver capabilities . . . 743
6.23.2 Build instructions . . . 743
6.23.2.1 Build crunch . . . 743
6.23.2.2 Build GDAL against crunch . . . 743
6.24 DERIVED -- Derived subdatasets driver . . . 743
6.24.1 Available functions . . . 744
6.24.2 Accessing derived subdatasets . . . 744
6.24.3 Listing available subdatasets . . . 746
6.24.4 See Also: . . . 748
6.25 DIMAP -- Spot DIMAP . . . 748
6.25.1 Driver capabilities . . . 748
6.26 DOQ1 -- First Generation USGS DOQ . . . 749
6.26.1 Driver capabilities . . . 749
6.27 DOQ2 -- New Labelled USGS DOQ . . . 749
6.27.1 Driver capabilities . . . 750
6.28 DTED -- Military Elevation Data . . . 750
6.28.1 Driver capabilities . . . 750
6.28.1.1 Configuration options . . . 750
6.28.2 Read Issues . . . 751
6.28.2.1 Read speed . . . 751
6.28.2.2 Georeferencing Issues . . . 751
6.28.2.3 Checksum Issues . . . 751
6.28.3 Creation Issues . . . 751
6.28.4 See Also . . . 752
6.29 E57: ASTM E57 3D file format (image part) . . . 752
6.29.1 Driver capabilities . . . 752
6.29.2 See Also . . . 752
6.30 ECRGTOC -- ECRG Table Of Contents (TOC.xml) . . . 752
6.30.1 Driver capabilities . . . 753
6.30.2 See Also . . . 753

6.31 ECW -- Enhanced Compressed Wavelets (.ecw) . . . 753
6.31.1 Driver capabilities . . . 754
6.31.2 Licensing . . . 754
6.31.3 History . . . 754
6.31.4 Creation Options . . . 754
6.31.5 Creation Options: . . . 755
6.31.6 Configuration Options . . . 755
6.31.6.1 ECW Version 3 Files . . . 756
6.31.6.2 ECWP . . . 756
6.31.6.3 Metadata / Georeferencing . . . 756
6.31.6.4 File Metadata Keys: . . . 756
6.31.7 Standalone plugin compilation . . . 757
6.31.8 See Also . . . 757
6.32 EEDAI - Google Earth Engine Data API Image . . . 758
6.32.1 Driver capabilities . . . 758
6.32.2 Dataset name syntax . . . 758
6.32.3 Open options . . . 758
6.32.4 Authentication methods . . . 758
6.32.5 Configuration options . . . 759
6.32.6 Overviews . . . 759
6.32.7 Subdatasets . . . 759
6.32.8 Metadata . . . 759
6.32.9 Pixel encoding . . . 759
6.32.9.1 Examples . . . 760
6.32.10 See Also . . . 760
6.33 EHdr -- ESRI .hdr Labelled . . . 760
6.33.1 Driver capabilities . . . 761
6.33.2 See Also . . . 761
6.34 EIR -- Erdas Imagine Raw . . . 761
6.34.1 Driver capabilities . . . 762
6.35 ENVI -- ENVI .hdr Labelled Raster . . . 762
6.35.1 Driver capabilities . . . 763
6.36 ESAT -- Envisat Image Product . . . 763
6.36.1 Driver capabilities . . . 764

6.161.1 Driver capabilities . . . 1155

7 Vector drivers **1157**
7.1 ADBC -- Arrow Database Connectivity . . . 1159
7.1.1 Google BigQuery support . . . 1159
7.1.2 Connection string . . . 1159
7.1.3 Dataset open options . . . 1160
7.1.4 "table_list" special layer . . . 1160
7.1.5 Custom driver entry point . . . 1160
7.1.6 Filtering . . . 1160
7.1.7 Examples . . . 1160
7.1.7.1 Example 1: Convert a Parquet file to GeoPackage . . . 1160
7.1.7.2 Example 2: Convert a DuckDB database to GeoPackage . . . 1161
7.1.8 See Also . . . 1161
7.2 ADBC BigQuery -- Google BigQuery through Arrow Database Connectivity . . . 1161
7.2.1 Runtime requirements . . . 1161
7.2.2 Dataset connection string . . . 1161
7.2.3 Dataset open options . . . 1161
7.2.4 Write support . . . 1162
7.2.5 Layer creation options . . . 1162
7.2.6 Examples . . . 1162
7.2.6.1 Example 1: Listing available tables from a BigQuery dataset . . . 1162
7.2.6.2 Example 2: Displaying the results of a SQL statement . . . 1163
7.2.6.3 Example 3: Converting a subset of a BigQuery table to a GeoPackage file . . . 1163
7.2.6.4 Example 4: Converting a GeoPackage file to a BigQuery table (provided the input table(s) use geographic coordinates): . . . 1163
7.2.6.5 Example 5: Converting a shapefile file to a BigQuery table, doing prior reprojection to WGS 84 (EPSG:4326), and renaming the layer . . . 1163
7.2.7 See Also . . . 1163
7.3 Artificial intelligence powered vector driver . . . 1163
7.3.1 Examples . . . 1164
7.4 AmigoCloud . . . 1164
7.4.1 Driver capabilities . . . 1164
7.4.2 Dataset name syntax . . . 1165
7.4.3 Authentication . . . 1165
7.4.4 Geometry . . . 1165
7.4.5 Filtering . . . 1165
7.4.6 Write support . . . 1165
7.4.7 Layer creation options . . . 1166
7.4.8 Configuration options . . . 1166
7.4.9 Examples . . . 1166
7.4.9.1 Example 1: Different ways to provide AmigoCloud API token . . . 1166
7.4.9.2 Example 2: Show list of datasets . . . 1166
7.4.9.3 Example 3: Accessing data from a list of datasets . . . 1167
7.4.9.4 Example 4: Creating and populating a table from a shapefile . . . 1167
7.4.9.5 Example 5: Append the data to an existing table (dataset id: 12345) from a shapefile 1167
7.4.9.6 Example 6: Overwriting the data of an existing table (dataset id: 12345) with data from a shapefile . . . 1167
7.4.9.7 Example 7: Delete existing dataset (dataset id: 12345) and create a new one with data from a shapefile . . . 1167

7.4.9.8 Example 8: Overwriting the data of an existing table (dataset id: 12345) with data from a shapefile. . . . 1167
7.4.10 See Also . . . 1167

CHAPTER

ONE

WHAT IS GDAL?

GDAL is a translator library for raster and vector geospatial data formats that is released under an MIT style Open Source *License* by the Open Source Geospatial Foundation. As a library, it presents a single raster abstract data model and single vector abstract data model to the calling application for all supported formats. It also comes with a variety of useful command line utilities for data translation and processing. The NEWS page describes the June 2026 GDAL/OGR 3.13.1 release.

See *Software using GDAL*

You may quote GDAL in publications by using the following Digital Object Identifier: DOI 10.5281/zenodo.5884351

CHAPTER

TWO

LICENSE

2.1 License

In general, the GDAL/OGR source code is licensed under the MIT license, whose terms are:

Permission is hereby granted, free of charge, to any person obtaining a copy of this software and associated documentation files (the "Software"), to deal in the Software without restriction, including without limitation the rights to use, copy, modify, merge, publish, distribute, sublicense, and/or sell copies of the Software, and to permit persons to whom the Software is furnished to do so, subject to the following conditions:

The above copyright notice and this permission notice shall be included in all copies or substantial portions of the Software.

THE SOFTWARE IS PROVIDED "AS IS", WITHOUT WARRANTY OF ANY KIND, EXPRESS OR IMPLIED, INCLUDING BUT NOT LIMITED TO THE WARRANTIES OF MERCHANTABILITY, FITNESS FOR A PARTICULAR PURPOSE AND NONINFRINGEMENT. IN NO EVENT SHALL THE AUTHORS OR COPYRIGHT HOLDERS BE LIABLE FOR ANY CLAIM, DAMAGES OR OTHER LIABILITY, WHETHER IN AN ACTION OF CONTRACT, TORT OR OTHERWISE, ARISING FROM, OUT OF OR IN CONNECTION WITH THE SOFTWARE OR THE USE OR OTHER DEALINGS IN THE SOFTWARE.

Some files are licensed under BSD 2-clause, BSD 3-clause or other non-copyleft licenses. The full licensing terms are available in the LICENSE.TXT file.

Note however that GDAL can be built against many dependencies, each of them with their own licensing terms (possibly LGPL, GPL or proprietary), hence the use of a GDAL binary can be subject to less permissive licensing terms than MIT, and it is the responsibility of users to check that they comply with the overall licensing terms.

CHAPTER

THREE

DOWNLOAD

The GDAL project distributes GDAL as source code and *Containers* only. *Binaries* produced by others are available for a variety of platforms and package managers.

```

3.1.2 Past Releases

Links to past releases are also available.

3.1.3 Development Source

The main repository for GDAL is located on GitHub at https://github.com/OSGeo/GDAL.

You can obtain a copy of the active source code by issuing the following command

```
git clone https://github.com/OSGeo/GDAL.git
```

Additional information is available about build_requirements and building_from_source.

3.1.4 Maintenance policy

The GDAL upstream team only maintains the branch on which the latest release has been done, with bugfixes releases issued roughly every 2 months. So, for example, during the development phase of GDAL 3.10.0, GDAL 3.9.x bugfixes releases are done based on the release/3.9 branch, but not older branches (GDAL 3.8.x or older).

3.2 Binaries

In this section we list a number of the binary distributions of GDAL all of which should have fully reproducible open source build recipes.

Note that the maintainers of those distributions are generally not the maintainers of the GDAL sources, so please report any issue specific to those builds through their own support channels.

3.2.1 Windows

Windows builds are available via Conda Forge (64-bit only). See the *Conda* or *pixi* section for more detailed information. GDAL is also distributed by GISInternals and OSGeo4W and through the NuGet and *vcpkg* package managers.

3.2.2 Linux

Packages are available for Debian, Alpine, Fedora, and other distributions.

3.2.3 Mac OS

GDAL packages are available on Homebrew.

3.2.4 Android

GDAL can be installed using *vcpkg*. You may also refer to vcpkg Android support for general instructions.

For example to install default configuration for the `arm64-android` target:

```
git clone https://github.com/Microsoft/vcpkg.git
cd vcpkg
./bootstrap-vcpkg.sh  # ./bootstrap-vcpkg.bat for Windows
./vcpkg integrate install
export ANDROID_NDK_HOME=/path/to/android_ndk_home  # to adapt
./vcpkg search gdal --featurepackages  # list optional features
./vcpkg install gdal:arm64-android  # install with default configuration
./vcpkg install gdal[poppler,netcdf]:arm64-android  # install with Poppler and netdf␣
↪support
```

3.2.5 Cross-Platform Package Managers

3.2.5.1 Conda

Conda can be used on multiple platforms (Windows, macOS, and Linux) to install software packages and manage environments. Conda packages for GDAL are available through conda-forge.

```
conda install [-c channel] [package...]
```

GDAL is available as several subpackages:

- `gdal`: Python bindings and Python utilities (depends on libgdal-core)
- `libgdal`: meta-package gathering all below libgdal-* packages (except libgdal-arrow-parquet)
- `libgdal-arrow-parquet`: *(Geo)Arrow IPC File Format / Stream* and *(Geo)Parquet* drivers as a plugin (depends on libgdal-core)
- `libgdal-avif`: *AVIF -- AV1 Image File Format* driver as a plugin (depends on libgdal-core, available since GDAL 3.10.0)
- `libgdal-core`: core library and C++ utilities, with a number of builtin drivers (available since GDAL 3.9.1)
- `libgdal-fits`: *FITS -- Flexible Image Transport System* driver as a plugin (depends on libgdal-core, available since GDAL 3.9.1)
- `libgdal-grib`: *GRIB -- WMO General Regularly-distributed Information in Binary form* driver as a plugin (depends on libgdal-core, available since GDAL 3.9.1)
- `libgdal-hdf4`: *HDF4 -- Hierarchical Data Format Release 4 (HDF4)* driver as a plugin (depends on libgdal-core, available since GDAL 3.9.1)
- `libgdal-hdf5`: *HDF5 -- Hierarchical Data Format Release 5 (HDF5)* driver as a plugin (depends on libgdal-core, available since GDAL 3.9.1)
- `libgdal-heif`: *HEIF / HEIC -- ISO/IEC 23008-12 High Efficiency Image File Format* driver as a plugin (depends on libgdal-core, available since GDAL 3.10.0)
- `libgdal-jp2openjpeg`: *JP2OpenJPEG -- JPEG2000 driver based on OpenJPEG library* driver as a plugin (depends on libgdal-core, available since GDAL 3.9.1)
- `libgdal-kea`: *KEA* driver as a plugin (depends on libgdal-core, available since GDAL 3.9.1)
- `libgdal-netcdf`: *NetCDF: Network Common Data Form* driver as a plugin (depends on libgdal-core, available since GDAL 3.9.1)
- `libgdal-pdf`: *PDF -- Geospatial PDF* driver as a plugin (depends on libgdal-core, available since GDAL 3.9.1)
- `libgdal-postgisraster`: *PostGISRaster -- PostGIS Raster driver* driver as a plugin (depends on libgdal-core, available since GDAL 3.9.1)
- `libgdal-pg`: *PostgreSQL / PostGIS* driver as a plugin (depends on libgdal-core, available since GDAL 3.9.1)
- `libgdal-tiledb`: *TileDB - TileDB raster* driver as a plugin (depends on libgdal-core, available since GDAL 3.9.1)
- `libgdal-xls`: *XLS - MS Excel format* driver as a plugin (depends on libgdal-core, available since GDAL 3.9.1)

For background on the GDAL package split on conda-forge, see Introducing Lightweight Versions of GDAL and PDAL.

To install the `gdal` package (Python bindings and utilities), and `libgdal-core`:

```
conda install -c conda-forge gdal
```

To install the `libgdal` meta-package with all available drivers, but libgdal-arrow-parquet:

```
conda install -c conda-forge libgdal
```

To install the Arrow and Parquet drivers as plugins:

```
conda install -c conda-forge libgdal-arrow-parquet
```

GDAL master Conda builds

GDAL master builds are available in the gdal-master channel. They are based on dependencies from the `conda-forge` channel. The latest master build can be installed with the following command:

```
conda install -c gdal-master -c conda-forge gdal-master::gdal
```

As with released versions of GDAL, additional drivers can be installed using `gdal-master::libgdal-{driver_name}`.

If you already have a GDAL master build installed in an environment, you can update it to the latest master version using the commands below. GDAL subpackages may need to be updated individually, because the master version numbers (e.g. `3.12.99`) do not change with every nightly build.

```
# check currently installed GDAL components and versions
conda list gdal
gdal --version
# remove current master version
conda remove gdal libgdal-core --yes
# install latest GDAL master build
conda install -c gdal-master -c conda-forge gdal libgdal-core --yes
gdal --version
```

3.2.5.2 pixi

Pixi is a package management tool for developers. It allows the developer to install libraries and applications in a reproducible way. Packages for GDAL are available through the conda-forge channel.

If you want to be able to use GDAL as part of a project:

```
pixi init name-of-project
cd name-of-project
pixi add gdal libgdal-core
pixi add libgdal-arrow-parquet # if you need the Arrow and Parquet drivers
pixi shell
```

Pixi supports using tools like GDAL and OGR globally, similar to conda's base environment, without having to use an activate command:

```
pixi global install gdal libgdal-core
pixi global install libgdal-arrow-parquet # if you need the Arrow and Parquet drivers
```

3.2.5.3 vcpkg

The GDAL port in the vcpkg dependency manager is kept up to date by Microsoft team members and community contributors. You can download and install GDAL using the vcpkg as follows:

```
git clone https://github.com/Microsoft/vcpkg.git
cd vcpkg
./bootstrap-vcpkg.sh  # ./bootstrap-vcpkg.bat for Windows
./vcpkg integrate install
./vcpkg search gdal --featurepackages  # list optional features
./vcpkg install gdal  # install with default configuration
./vcpkg install gdal[poppler,netcdf]  # install with Poppler and netdf support
```

If the version is out of date, please create an issue or pull request on the vcpkg repository.

3.2.5.4 Spack

Spack is a package management tool designed to support multiple versions and configurations of software on a wide variety of platforms and environments. It was designed for large supercomputing centers. Spack builds packages from sources, and allows tweaking their configurations.

You can find information about GDAL in Spack at https://packages.spack.io/package.html?name=gdal

For the default GDAL build with a reduced number of drivers:

```
git clone -c feature.manyFiles=true https://github.com/spack/spack.git
cd spack/bin
./spack install gdal
```

For a build with netcdf driver enabled:

```
./spack install gdal +netcdf
```

3.3 Containers

Docker images with nightly builds of GDAL master and tagged releases are available at GitHub Container registry.

Information on the content of the different configurations can be found at https://github.com/OSGeo/gdal/tree/master/docker.

3.4 Documentation

This documentation is also available as a PDF for offline browsing.

CHAPTER

FOUR

FAQ

4.1 What does GDAL stand for?

GDAL - Geospatial Data Abstraction Library

It is sometimes pronounced "goo-doll" (a bit like goo-gle), while others pronounce it "gee-doll," and others pronounce it "gee-dall."

Listen how Frank Warmerdam pronounces it and the history behind the acronym.

4.2 What is this OGR stuff?

OGR used to be a separate vector IO library inspired by OpenGIS Simple Features which was separated from GDAL. With the GDAL 2.0 release, the GDAL and OGR components were integrated together.

4.3 What does OGR stand for?

See OGR.

4.4 What does CPL stand for?

See CPL.

4.5 What does VSI stand for?

See VSI.

4.6 When was the GDAL project started?

In late 1998, Frank Warmerdam started to work as independent professional on the GDAL/OGR library.

4.7 Is GDAL/OGR proprietary software?

No, GDAL/OGR is a Free and Open Source Software.

4.8 What license does GDAL/OGR use?

See *License*

4.9 What operating systems does GDAL-OGR run on?

You can use GDAL/OGR on all modern flavors of Unix: Linux, FreeBSD, Mac OS X; all supported versions of Microsoft Windows; mobile environments (Android and iOS). Both 32-bit and 64-bit architectures are supported.

4.10 Is there a graphical user interface to GDAL/OGR?

Plenty! Among the available options, QGIS is an excellent free and open source application with a rich graphical user interface. It allows users to display most GDAL raster and vector supported formats and provides access to most GDAL utilities through its Processing toolbox.

You can also consult the *list of software using GDAL*.

4.10.1 Software using GDAL

4.10.1.1 Free and open source

- actinia A cloud based geoprocessing platform from mundialis (GPL v3)
- Biodiverse A tool for the spatial analysis of diversity. Uses GDAL for import/export of data (GPL v3)
- Bluemapia Multi-Map(Google,Microsoft,Open Street Map, NOAA/BSB Charts,self-calibrated raster) location-based GPS app for Windows Mobile. (GPL v2)
- BRL-CAD An open source solid modeling computer-aided design system.
- Demeter Another OpenGL based terrain engine somewhat similar to VTP.
- DuckDB Spatial Extension: Spatial extension for DuckDB
- EOxServer OGC-compliant server for Earth Observation (EO) data supporting WMS and WCS with EO application profiles (EOxServer Open License)
- exactextract Fast and accurate raster/vector zonal statistics (Apache 2.0)
- Feature Data Objects (FDO) Open source spatial data access libraries (LGPL)
- Fiona Fiona is OGR's neater Python API – sleek and elegant on the outside, indomitable power on the inside.
- gdal3.js.org Convert raster and vector geospatial data to various formats and coordinate systems entirely in the browser.
- *GdalToTiles* C# Program (open source) for making image tiles for Google Earth with KML Superoverlay. (project discontinued; was hosted on CodePlex which shut down in December 2017)
- GeoDa Introduction to Spatial Data Analysis (spatial autocorrelation and spatial regression) (GPL)
- GeoDjango A framework for building geographic web applications.
- geofileops Python toolbox to process large vector files faster.
- GeoKettle An open source spatial ETL (Extract, Transform and Load) tool (LGPL)
- GeoNotebook a Jupyter notebook extension for geospatial visualization and analysis. (Apache 2.0)
- GeoServer a open source software server written in Java that allows users to share and edit geospatial data.

- GMT (Generic Mapping Tools) an open source collection of tools for processing and displaying xy and xyz datasets.
- GRASS GIS A raster/vector open source GIS that uses GDAL for raster/vector import and export (via r.in.gdal/r.out.gdal)
- gstat a geostatistical modelling package.
- GuidosToolbox A multi-platform desktop application for generic image object analysis.
- gvSIG Desktop GIS Client.
- ILWIS Remote Sensing and GIS Desktop Package.
- Image I/O-Ext includes gdalframework, a framework leveraging on GDAL via SWIG's generated JAVA bindings to provide support for a broad set of data formats.
- libLAS Open Source LAS 1.0/1.1 ASPRS LiDAR data translation toolset
- Loader A simple loader for geographic data in GML and KML that needs some preparation before loading via ogr2ogr.
- MapGuide Open source web mapping server.
- Mapnik C++/ Python mapping toolkit
- MapServer A popular web mapping application with GDAL support.
- MapWindow open source ActiveX control with GIS functionality.
- Mergin Maps Field data collection app built on top of QGIS with cloud sync.
- MultiSpec Application for interactively analyzing multispectral/hyperspectral image data.
- NASA Ames Stereo Pipeline Software for creating terrain models and ortho images from planetary stereo images. (Apache 2.0)
- NASA WorldWind Multiplatform virtual globe library to quickly and easily create interactive visualizations of 3D globes, map and geographical information.
- NextGIS Formbuilder Desktop application for creating and editing forms.
- NextGIS Web Server-side Web GIS and a framework for storage, visualization and permissions management of all kinds
- Ogr2 GUI Graphical user interface for ogr2ogr
- OpenCPN A concise ChartPlotter/Navigator. A cross-platform ship-borne GUI application.
- OpenDataCube FOSS software package that simplifies the management and analysis of large amounts of satellite imagery and other Earth observation data.
- OpenEV An OpenGL/GTK/Python based graphical viewer which exclusively uses GDAL for raster access.
- OFGT a collection of utilities for multipurpose forest monitoring under the Open Foris Initiative Open Foris Initiative.
- OpenFLUID a software platform for spatial modelling of landscapes dynamics
- OpenSceneGraph 3D rendering engine with osgdem and osgEarth plugins.
- Opticks an open source remote sensing application and development framework, with a GDAL plugin.
- Orfeo Toolbox (OTB) a general remote sensing image processing library.
- OSSIM Another geospatial viewing and analysis environment which uses GDAL as one of several plugins.
- PDAL Point Cloud Data Abstraction Library

- pktools open source (GPLv3) tools written in C++ for remote sensing image processing
- PNMapcalc A raster map calculator with C-like scripting language.
- PostGIS spatial database extender for PostgreSQL: The raster loader and many of the raster SQL functions rely on GDAL.
- PostgreSQL OGR Foreign Data Wrapper Expose OGR layer as PostgreSQL foreign tables.
- QGIS A cross platform desktop GIS.
- R A free software environment for statistical computing and graphics, with bindings to GDAL via the rgdal package.
- Rasterio Python library and command line utilities to read and write GDAL rasters.
- Rasterix A cross platform open source utility to process raster data based on Qt and GDAL.
- SAGA GIS A free geographic information system (GIS), with a special 'Application Programming Interface' (API) for geographic data processing.
- SNAP Sentinel Application Platform for Earth Observation processing and analysis.
- StarSpan raster/vector analysis.
- t-rex Vector tile server written in Rust.
- Thuban A multi-platform interactive geographic data viewer.
- Vertual Terrain Project fostering tools for easy construction of the real world in interactive, 3D digital form.
- ViRGiS Creating a GIS Platform in Virtual Reality / Mixed Reality

4.10.1.2 Proprietary license / Other

- 3D DEM Viewer from MS MacroSystem.
- Cadcorp SIS: A Windows GIS with a GDAL and OGR plugins.
- Carmenta Engine (previously known as SpatialAce): A GIS Rapid Application Development environment
- CARTO A cloud mapping platform to analyze and visualize geospatial data.
- CatchmentSIM A Windows terrain analysis model for hydrologic applications.
- Daylon Leveller A terrain/heightfield/bumpmap modeler
- ERDAS ER Viewer Image viewer for very large JPEG 2000 and ECW files.
- ESRI ArcGIS Pro A popular GIS platform.
- Eternix Blaze Advanced geo-spatial visualization application and SDK.
- FalconView Windows-based GIS platform with roots in military mission planning, now available as a free GIS visualization and analysis package.
- flighttrack GPS track viewing and downloading software for Mac.
- FME A GIS translator package includes a GDAL plugin.
- GenGIS Software for geospatial analysis of genetic data.
- Geographic Imager DEM / aerial / satellite image processing GIS plug-in for Adobe Photoshop, by Avenza Systems.
- GeoDMS A framework for building spatial calculation models.
- GeoFusion 3D visualization.

- Geoweb3d A 3D virtual globe that provides on-the-fly, game-quality visualization of GIS data.
- Google Earth A 3D world viewer.
- HydroDaVE Explorer A web-enabled client that provides users an easy to use, secure, and reliable data management platform to efficiently manage, access, and analyze environmental data.
- IDRISI A GIS and Image Processing Windows Desktop application. Uses GDAL to import/export/warp raster data.
- Infraworks a BIM software for infrastructure project design, part of the Autodesk suite.
- iShare Web data integration and publishing platform by Astun Technology.
- Makai Voyager An advanced 3D/4D geospatial visualization platform.
- MapInfo Professional Desktop GIS and mapping application
- MapTiler Generator of tiles for interactive maps and overlays made from raster images and geodata.
- Maptitude Mapping Software Desktop GIS and business mapping application
- MicroImages TNT advanced software for geospatial analysis (Windows, Linux, Mac OS X and UNIX)
- Micromine A mining software solution that uses GDAL for reading/writing various geospatial file formats.
- Mirone Matlab based package for geospatial, oceanographic and geophysical analysis of grids
- MyGeodata Cloud Online converter of GDAL raster and OGR vector formats
- OPALS Orientation and Processing of Airborne Laser Scanning Data
- Procura Landholding inspection system developed for the UK Homes and Communities Agency. GDAL is used for checking out background mapping.
- ScanMagic Win32 application for visualization, analysis and processing of remote sensing data.
- Scalable Algorithmics (SCALGO) Software for efficiently constructing and performing computations on very large raster and TIN terrain models.
- Scenomics Software for building terrain databases uses GDAL for projection and data import/export.
- scenProc scenProc: A tool to create scenery for Microsoft Flight Simulator and Lockheed Martin Prepar3D by processing G
- SeaView A 3D GIS package for geophysical and hydrographical data (side scan sonar, subbottom profiler, magnetometer, multibeam, etc.
- SkylineGlobe The Skyline suite of interactive applications allows you to build, view, query and analyze customized, virtual 3D landscapes.
- SpacEyes3D 3D visualization software for cartographic data.
- Spatial Manager A product suite designed designed to manage spatial data in a simple, fast and inexpensive way. Uses GDAL to import/export data.
- TacitView An imagery visualization and exploitation package for military intelligence.
- TatukGIS Desktop GIS mapping and data editing application.
- Team Awareness Kit Suite of georeferenced imagery and situational awareness tools developed for military planning and execution, now available for civilian use.
- TerrainView Interactive real-time 3D GIS Software.
- TransCAD GIS Desktop Transportation Analysis Software
- TravTime .NET Application for visualizing, processing and analyzing GPS data for travel time, speed, and de

- VectorWorks The Vectorworks line of software products provides professional design solutions in the AEC, entertainment and landscape design industries.
- WindNinja wind model for fire behavior modeling.

4.11 What compiler can I use to build GDAL/OGR?

GDAL/OGR must be compiled with a C++17 capable compiler since GDAL 3.9 (C++11 in previous versions)

Build requirements are described in build_requirements.

4.12 I have a question that's not answered here. Where can I get more information?

See *Community*

Keep in mind, the quality of the answer you get does bear some relation to the quality of the question. If you need more detailed explanation of this, you can find it in essay How To Ask Questions The Smart Way by Eric S. Raymond.

4.13 How do I add support for a new format?

To some extent this is now covered by the *Raster driver implementation tutorial* and *Vector driver implementation tutorial*

4.14 What about file formats for 3D models?

While some vector drivers in GDAL support 3D geometries (e.g. reading CityGML or AIXM through the GML driver, or 3D geometries in GeoPackage), 3-dimensional scenes or models formats (such as glTF, OBJ, 3DS, etc.) are out-of-scope for GDAL. Users may consider a library such as ASSIMP (Open-Asset-Importer-Library) for such formats.

4.15 Is GDAL thread-safe ?

See *Multi-threading*

4.16 Does GDAL provide a Section 508 information?

No, GDAL itself is an open-source software and project, not a Vendor. If your organization considers they need a VPAT or Section 508 form to be able to use GDAL, it is their responsibility to complete the needed steps themselves.

4.17 How do I cite GDAL ?

See CITATION

CHAPTER

FIVE

PROGRAMS

5.1 "gdal" application

Added in version 3.11.

Starting with GDAL 3.11, parts of the GDAL utilities are available from a new single **gdal** program that accepts commands and subcommands.

As an introduction, you can follow the webinar given on June 3, 2025 about the GDAL Command Line Interface Modernization as a PDF slide deck or the recording of the video.

> **Warning**
>
> The **gdal** command is provisionally provided as an alternative interface to GDAL and OGR command line utilities. The project reserves the right to modify, rename, reorganize, and change the behavior of the utility until it is officially frozen via PSC vote in a future major GDAL release. The utility needs time to mature, benefit from incremental feedback, and explore enhancements without carrying the burden of full backward compatibility. Your usage of it should have no expectation of compatibility until that time.

5.1.1 General

5.1.1.1 Main gdal entry point

Added in version 3.11.

Synopsis

```
Usage: gdal <COMMAND> [OPTIONS]
where <COMMAND> is one of:
  - convert:  Convert a dataset (shortcut for 'gdal raster convert' or 'gdal vector␣
↪convert').
  - dataset:  Commands to manage datasets.
  - driver:   Command for driver specific operations.
  - info:     Return information on a dataset (shortcut for 'gdal raster info' or 'gdal␣
↪vector info').
  - mdim:     Multidimensional commands.
  - pipeline: Process a dataset applying several steps.
  - raster:   Raster commands.
  - vector:   Vector commands.
  - vsi:      GDAL Virtual System Interface (VSI) commands.
```

(continues on next page)

(continued from previous page)

```
Common Options:
  -h, --help              Display help message and exit
  --json-usage            Display usage as JSON document and exit
  --config <KEY>=<VALUE>  Configuration option [may be repeated]

Options:
  --version               Display GDAL version and exit
  --drivers               Display driver list as JSON document

'gdal <FILENAME>' can also be used as a shortcut for 'gdal info <FILENAME>'.
And 'gdal read <FILENAME> ! ...' as a shortcut for 'gdal pipeline <FILENAME> ! ...'.
```

Return status code

The program returns status code 0 in case of success, and non-zero in case of error (non-blocking errors emitted as warnings are considered as a successful execution).

Examples

Example 1: Display the GDAL version

```
$ gdal --version
GDAL 3.14.0dev-687b2cae6c, released 2026/06/05 (debug build)
```

Example 2: Getting information on the file utm.tif (with JSON output)

```
$ gdal info utm.tif
```

Example 3: Converting file utm.tif to GeoPackage raster

```
$ gdal convert utm.tif utm.gpkg
```

Example 4: Getting information on all available commands and subcommands as a JSON document.

```
$ gdal --json-usage
```

Example 5: Getting list of all formats supported by the current GDAL build, as text

```
$ gdal --formats
```

Example 6: Search for Parquet in the list of all formats using jq

Bash

PowerShell

```
$ gdal --drivers | jq '.[] | select(.short_name == "Parquet")'
```

```
gdal --drivers | jq '.[] | select(.short_name == \"Parquet\")'
```

5.1.1.2 Syntax for commands of `gdal` program

Added in version 3.11.

- Commands accept one or several positional arguments, typically for dataset names. The order is input(s) first, output last.

  Positional arguments can also be specified as named arguments, if preferred to avoid any ambiguity.

- Named arguments have:

  - at least one "long" name, preceded by two dash characters when specified on the command line,
  - optionally auxiliary long names,
  - and optionally a one-letter short name, preceded by a single dash character on the command line.

  e.g. `-f, --of, --format, --output-format <OUTPUT-FORMAT>`

  Boolean arguments (also called flags) are enabled by specifying the argument name without a value.

  e.g. `--overwrite`

  Arguments that require a value are specified like:

  - `-f VALUE` for one-letter short names.
  - `--format VALUE` or `--format=VALUE` for long names.

  Some arguments can be multi-valued. Some of them require all values to be packed together and separated by commas. This is, for example, the case of `--bbox <BBOX> Clipping bounding box as xmin,ymin, xmax,ymax`. e.g. `--bbox=2.1,49.1,2.9,49.9`

  Others accept each value to be preceded by a new mention of the argument name. e.g `--co COMPRESS=LZW --co TILED=YES`. In this example, if the value of the argument does not contain commas, the packed form is also accepted: `--co COMPRESS=LZW,TILED=YES`.

- Named arguments can be placed before or after positional arguments.

Example

Given the following (simplified) synopsis:

```
gdal raster convert [OPTIONS] <INPUT> <OUTPUT>

Convert a raster dataset.

Positional arguments:
  -i, --input <INPUT>                                    Input raster dataset [required]
  -o, --output <OUTPUT>                                  Output raster dataset (created by␣
↪algorithm) [required]

Options:
  -f, --of, --format, --output-format <OUTPUT-FORMAT>  Output format
  --co, --creation-option <KEY>=<VALUE>                  Creation option [may be repeated]
  --overwrite                                            Whether overwriting existing␣
↪output is allowed
```

The following command lines are valid:

```
gdal raster convert input.tif output.tif
gdal raster convert -i input.tif -o output.tif
gdal raster convert --input=input.tif --output=output.tif
gdal raster convert --input input.tif --output output.tif
gdal raster convert --creation-option COMPRESS=LZW --creation-option TILED=YES --
↪overwrite input.tif output.tif
gdal raster convert input.tif output.tif --co COMPRESS=LZW,TILED=YES --overwrite
```

Working with JSON Output

Several GDAL commands can produce JSON output. jq is a useful tool to parse this JSON and extract specific information. Precompiled binaries of jq are available for Linux, macOS, and Windows.

Some example workflows are listed below:

- *Search for Parquet in the list of all formats using `jq`*
- *List all layers and their geometry fields using `jq`*

Suggestions for argument values

As an alternative to *Bash completion for gdal*, it is possible to ask for potential enumerated values for certain arguments by appending =? to the argument name. This feature is available in all shells and on all operating systems.

Example 1: Asking for the layer names of a vector dataset

```
gdal vector info my.gpkg --layer=?
```

can return:

```
ERROR 1: info: Potential values for argument 'layer' are:
- towns
- countries
```

Example 2: Asking for the allowed values of the resampling argument

```
gdal raster reproject --resampling=?
```

returns:

```
ERROR 1: reproject: Potential values for argument 'resampling' are:
- nearest
- bilinear
- cubic
- cubicspline
- lanczos
- average
- rms
- mode
- min
- max
- med
- q1
```

(continues on next page)

(continued from previous page)

```
- q3
- sum
```

5.1.1.3 Migration guide to gdal command line interface

This page documents, through examples, how to migrate from the traditional GDAL command line utilities to the unified gdal command line interface added in GDAL 3.11.

Raster commands

- Getting information on a raster dataset in human-readable format

```
gdalinfo my.tif

==>

gdal raster info my.tif
```

- Converting a georeferenced netCDF file to cloud-optimized GeoTIFF

```
gdal_translate -of COG in.nc out.tif

==>

gdal raster convert --of=COG in.nc out.tif
```

- Reprojecting a GeoTIFF file to a Deflate compressed tiled GeoTIFF file

```
gdalwarp -t_srs EPSG:4326 -co TILED=YES -co COMPRESS=DEFLATE -overwrite in.tif out.tif

==>

gdal raster reproject --output-crs=EPSG:4326 --co=TILED=YES,COMPRESS=DEFLATE --overwrite␣
↪in.tif out.tif
```

- Update existing out.tif with content of in.tif using cubic interpolation

```
gdalwarp -r cubic in.tif out.tif

==>

gdal raster update -r cubic in.tif out.tif
```

- Converting a PNG file to a tiled GeoTIFF file, adding georeferencing for world coverage in WGS 84 and metadata

```
gdal_translate -a_ullr -180 90 180 -90 -a_srs EPSG:4326 -co TILED=YES -mo␣
↪DESCRIPTION=Mean_day_temperature in.png out.tif

==>

gdal raster pipeline read in.png ! edit --crs=EPSG:4326 --bbox=-180,-90,180,90 --
↪metadata=DESCRIPTION=Mean_day_temperature ! write --co=TILED=YES out.tif
```

Note that the order of elements differ: "upper-left-x upper-left-y lower-right-x lower-right-y" for gdal_translate, compared to "minimum-x,minimum-y,maximum-x,maximum-y" for the `--bbox` option of "gdal raster pipeline ... edit".

- Clipping a raster with a bounding box

```
gdal_translate -projwin 2 50 3 49 in.tif out.tif

==>

gdal raster clip --bbox=2,49,3,50 in.tif out.tif
```

- Creating a virtual mosaic (.vrt) from all GeoTIFF files in a directory

```
gdalbuildvrt out.vrt src/*.tif

==>

gdal raster mosaic src/*.tif out.vrt
```

- Creating a mosaic in COG format from all GeoTIFF files in a directory

```
gdalbuildvrt tmp.vrt src/*.tif
gdal_translate -of COG tmp.vrt out.tif

==>

gdal raster mosaic --of=COG src/*.tif out.tif
```

- Adding internal overviews for reduction factors 2, 4, 8 and 16 to a GeoTIFF file

```
gdaladdo -r average my.tif 2 4 8 16

==>

gdal raster overview add -r average --levels=2,4,8,16 my.tif
```

- Combining single-band rasters into a multi-band raster

```
gdalbuildvrt tmp.vrt red.tif green.tif blue.tif
gdal_translate tmp.vrt out.tif

==>

gdal raster stack red.tif green.tif blue.tif out.tif
```

- Reorder a 3-band dataset with bands ordered Blue, Green, Red to Red, Green, Blue

```
gdal_translate -b 3 -b 2 -b 1 bgr.tif rgb.tif

==>

gdal raster select --band 3,2,1 bgr.tif rgb.tif --overwrite
```

- Expand a dataset with a color table to RGB

```
gdal_translate -expand rgb color_table.tif rgb.tif

==>

gdal raster color-map color_table.tif rgb.tif --overwrite
```

- Apply an external color-map to a dataset

```
gdaldem color-map color_table.tif color_map.txt rgb.tif

==>

gdal raster color-map --color-map=color_map.txt color_table.tif rgb.tif --overwrite
```

- Convert nearly black values of the collar to black

```
nearblack -nb 1 -near 10 my.tif

==>

gdal raster clean-collar --update --color-threshold=1 --pixel-distance=10 my.tif
```

- Generating tiles between zoom level 2 and 5 of WebMercator from an input GeoTIFF

```
gdal2tiles --zoom=2-5 input.tif output_folder

==>

gdal raster tile --min-zoom=2 --max-zoom=5 input.tif output_folder
```

Vector commands

- Getting information on a vector dataset in human-readable format

```
ogrinfo -al -so my.gpkg

==>

gdal vector info my.gpkg
```

- Converting a shapefile to a GeoPackage

```
ogr2ogr out.gpkg in.shp

==>

gdal vector convert in.shp out.gpkg
```

- Reprojecting a shapefile to a GeoPackage

```
ogr2ogr -t_srs EPSG:4326 out.gpkg in.shp

==>
```

(continues on next page)

(continued from previous page)

```
gdal vector reproject --output-crs=EPSG:4326 in.shp out.gpkg
```

- Clipping a GeoPackage file

```
ogr2ogr -clipsrc 2 49 3 50 out.gpkg in.shp

==>

gdal vector clip --bbox=2,49,3,50 in.gpkg out.gpkg
```

- Selecting features from a GeoPackage file intersecting a bounding box, but not clipping them to it

```
ogr2ogr -spat 2 49 3 50 out.gpkg in.shp

==>

gdal vector filter --bbox=2,49,3,50 in.gpkg out.gpkg
```

- Selecting features from a shapefile intersecting a bounding box, but not clipping them to it and reprojecting

```
ogr2ogr -t_srs EPSG:32631 -spat 2 49 3 50 out.gpkg in.shp

==>

gdal vector pipeline read in.gpkg ! filter --bbox=2,49,3,50 ! reproject --output-
↪crs=EPSG:32631 ! write out.gpkg
```

- Selecting features from a shapefile based on an attribute query, and restricting to a few fields

```
ogr2ogr -where "country='Greenland'" -select population,_ogr_geometry_ out.gpkg in.shp

==>

gdal vector pipeline ! read in.shp ! filter --where "country='Greenland'" ! select --
↪fields population,_ogr_geometry_ ! write out.gpkg
```

- Creating a GeoPackage stacking all input shapefiles in separate layers.

```
ogrmerge -f GPKG -o merged.gpkg *.shp

==>

gdal vector concat --mode=stack *.shp merged.gpkg
```

- Modify in-place a GeoPackage dataset by running a SQL command.

```
ogrinfo my.gpkg -sql "DELETE FROM countries WHERE pop > 1e6"

==>

gdal vector sql --update my.gpkg --sql "DELETE FROM countries WHERE pop > 1e6"
```

Python commands

The following commands were previously provided as individual *Python scripts*, but are now accessible through the unified "gdal" command-line interface.

- Listing the contents of a remote *PMTiles* dataset, using *gdal vsi list*.

```
python gdal_ls.py -lr "/vsipmtiles//vsicurl/https://protomaps.github.io/PMTiles/
↪protomaps(vector)ODbL_firenze.pmtiles"

==>

gdal vsi list -lR "/vsipmtiles//vsicurl/https://protomaps.github.io/PMTiles/
↪protomaps(vector)ODbL_firenze.pmtiles"
```

- Listing the contents of a vsis3 dataset.

```
export AWS_NO_SIGN_REQUEST="YES"
gdal_ls.py "/vsis3/overturemaps-us-west-2/release/2025-10-22.0/theme=buildings/
↪type=building"

==>

export AWS_NO_SIGN_REQUEST="YES"
gdal vsi list "/vsis3/overturemaps-us-west-2/release/2025-10-22.0/theme=buildings/
↪type=building"
```

- Extracting all remote content into a local directory, using *gdal vsi copy*.

```
gdal_cp.py "/vsipmtiles//vsicurl/https://protomaps.github.io/PMTiles/
↪protomaps(vector)ODbL_firenze.pmtiles/metadata.json" /vsistdout/ | jq

==>

gdal vsi copy -r "/vsipmtiles//vsicurl/https://protomaps.github.io/PMTiles/
↪protomaps(vector)ODbL_firenze.pmtiles" out_pmtiles
```

5.1.1.4 Bash completion for `gdal`

Added in version 3.11.

If Bash is used as an interactive shell, users can benefit from completion, using the <TAB> key. Bash completion is enabled by first sourcing the `$install_prefix/share/bash-completion/completions/gdal` file, which should be automatically done on a number of binary distributions of GDAL.

That script can also be sourced when using **zsh** as a shell (starting with GDAL 3.11.1)

Examples of completion

Example 1: Listing sub-commands of "gdal":

```
$ gdal <TAB><TAB>
==>
convert   info      pipeline  raster    vector
```

Example 2: Completion of a sub-command from its initial letters:

```
$ gdal r<TAB>
==>
$ gdal raster
```

Example 3: Listing sub-commands of "gdal raster":

```
$ gdal raster<TAB><TAB>
==>
convert    edit       info       pipeline   reproject
```

Example 4: Listing switches of "gdal raster"

```
$ gdal raster -<TAB><TAB>
==>
--approx-stats   -f               --help           --if             --json-usage     --
↪min-max         --no-fl          --no-md          --oo             --stats
--checksum       --format         --hist           --input          --list-mdd       --
↪mm              --no-gcp         --no-nodata      --open-option    --subdataset
--drivers        -h               -i               --input-format   --mdd            --
↪no-ct           --no-mask        --of             --output-format  --version
```

Example 5: Listing allowed values for a switch

```
$ gdal raster info --of=<TAB><TAB>
==>
json  text
```

Example 6: Listing allowed creation options, restricted to those valid for the output format, once the output filename has been specified

```
$ gdal raster convert in.tif out.tif --co <TAB><TAB>
==>
ALPHA=                           ENDIANNESS=                      JXL_EFFORT=           ␣
↪          PIXELTYPE=                       SOURCE_PRIMARIES_RED=            TIFFTAG_
↪TRANSFERRANGE_BLACK=
BIGTIFF=                         GEOTIFF_KEYS_FLAVOR=             JXL_LOSSLESS=         ␣
↪          PREDICTOR=                       SOURCE_WHITEPOINT=               TIFFTAG_
↪TRANSFERRANGE_WHITE=
BLOCKXSIZE=                      GEOTIFF_VERSION=                 LZMA_PRESET=          ␣
↪          PROFILE=                         SPARSE_OK=                       TILED=
[ ... snip ... ]
```

Example 7: Listing known configuration options starting with AWS

```
$ gdal --config AWS_<TAB><TAB>
==>
AWS_ACCESS_KEY_ID=                       AWS_DEFAULT_REGION=                      AWS_
```

(continues on next page)

(continued from previous page)

```
↪REQUEST_PAYER=                        AWS_STS_ENDPOINT=
AWS_CONFIG_FILE=                         AWS_HTTPS=                              AWS_
↪ROLE_ARN=                             AWS_STS_REGION=
AWS_CONTAINER_AUTHORIZATION_TOKEN=       AWS_MAX_KEYS=                           AWS_
↪ROLE_SESSION_NAME=                    AWS_STS_REGIONAL_ENDPOINTS=
AWS_CONTAINER_AUTHORIZATION_TOKEN_FILE=  AWS_NO_SIGN_REQUEST=                    AWS_S3_
↪ENDPOINT=                           AWS_TIMESTAMP=
AWS_CONTAINER_CREDENTIALS_FULL_URI=      AWS_PROFILE=                            AWS_
↪SECRET_ACCESS_KEY=                    AWS_VIRTUAL_HOSTING=
AWS_DEFAULT_PROFILE=                     AWS_REGION=                             AWS_
↪SESSION_TOKEN=                        AWS_WEB_IDENTITY_TOKEN_FILE=
```

Example 8: Auto-completion of EPSG CRS codes

```
$ gdal raster reproject --output-crs EPSG:432<TAB>
==>
4322 -- WGS 72                  4324 -- WGS 72BE                4326 -- WGS 84          ␣
↪       4327 -- WGS 84 (geographic 3D)  4328 -- WGS 84 (geocentric)     4329 -- WGS 84␣
↪(3D)
```

Example 9: Auto-completion of filenames in a cloud storage (assuming credentials are properly set up)

```
$ gdal raster info /vsis3/my_bucket/b<TAB><TAB>
==>
/vsis3/my_bucket/byte.tif      /vsis3/my_bucket/byte2.tif
```

5.1.1.5 How to use `gdal` CLI algorithms from C

Added in version 3.12.

The C API for `gdal` CLI algorithms is available in `gdalalgorithm.h`.

The first step is to get the instance of the `GDALGlobalAlgorithmRegistry` with *GDALGetGlobalAlgorithmRegistry()* and then call *GDALAlgorithmRegistryInstantiateAlgFromPath()* with the path of the algorithm. Once done with a `GDALAlgorithmRegistryH` handle, the memory associated to it can be released with *GDALAlgorithmRegistryRelease()* (the algorithm handles got from the registry will still be valid).

For example:

```
GDALAlgorithmRegistryH hRegistry = GDALGetGlobalAlgorithmRegistry();
const char *const papszAlgPath[] = { "raster", "reproject", NULL };
GDALAlgorithmH hAlg = GDALAlgorithmRegistryInstantiateAlgFromPath(hRegistry,␣
↪papszAlgPath);
GDALAlgorithmRegistryRelease(hRegistry);
```

Arguments can be queried with *GDALAlgorithmGetArg()* and set through different setters depending on the type of the argument, such as *GDALAlgorithmArgSetAsString()*, *GDALAlgorithmArgSetAsInteger()*, *GDALAlgorithmArgSetAsDouble()*, etc. Once done with the argument handle, it must be released with *GDALAlgorithmArgRelease()*.

For example:

```
{
    GDALAlgorithmArgH hArg = GDALAlgorithmGetArg(hAlg, "input");
    GDALAlgorithmArgSetAsString(hArg, "byte.tif");
    GDALAlgorithmArgRelease(hArg);
}
{
    GDALAlgorithmArgH hArg = GDALAlgorithmGetArg(hAlg, "resolution");
    const double res[] = {60, 60};
    GDALAlgorithmArgSetAsDoubleList(hArg, 2, res);
    GDALAlgorithmArgRelease(hArg);
}
```

Execution of the algorithm is performed by *GDALAlgorithmRun()*, with an optional progress function. Proper closing of the output dataset must be performed with *GDALAlgorithmFinalize()*. Once done with the algorithm handle, it must be released with *GDALAlgorithmFinalize()*.

```
int ret = 0;
if( GDALAlgorithmRun(hAlg, NULL, NULL) )
{
    // do something
    GDALAlgorithmArgRelease(hArg);
}
else
{
    fprintf(stderr, "failure\n");
    ret = 1;
}
GDALAlgorithmFinalize(hAlg);
GDALAlgorithmRelease(hAlg);
```

When outputting to a *MEM -- In Memory datasets* dataset, you typically want to get the output dataset with:

```
GDALAlgorithmArgH hArg = GDALAlgorithmGetArg(hAlg, "output");
GDALArgDatasetValueH hVal = GDALAlgorithmArgGetAsDatasetValue(hArg);
GDALDatasetH hDS = GDALArgDatasetValueGetDatasetRef(hVal);
```

Putting all things together:

```
#include "gdal.h"
#include "gdalalgorithm.h"

#include <stdio.h>

int main()
{
    GDALAllRegister();
    GDALAlgorithmRegistryH hRegistry = GDALGetGlobalAlgorithmRegistry();
    const char *const papszAlgPath[] = { "raster", "reproject", NULL };
    GDALAlgorithmH hAlg = GDALAlgorithmRegistryInstantiateAlgFromPath(hRegistry,␣
↪papszAlgPath);
    GDALAlgorithmRegistryRelease(hRegistry);
    if( !hAlg )
    {
```

(continues on next page)

(continued from previous page)

```
        fprintf(stderr, "cannot instantiate algorithm\n");
        return 1;
    }

    {
        GDALAlgorithmArgH hArg = GDALAlgorithmGetArg(hAlg, "input");
        GDALAlgorithmArgSetAsString(hArg, "byte.tif");
        GDALAlgorithmArgRelease(hArg);
    }

    {
        GDALAlgorithmArgH hArg = GDALAlgorithmGetArg(hAlg, "output-format");
        GDALAlgorithmArgSetAsString(hArg, "MEM");
        GDALAlgorithmArgRelease(hArg);
    }

    {
        GDALAlgorithmArgH hArg = GDALAlgorithmGetArg(hAlg, "dst-crs");
        GDALAlgorithmArgSetAsString(hArg, "EPSG:26711");
        GDALAlgorithmArgRelease(hArg);
    }

    {
        GDALAlgorithmArgH hArg = GDALAlgorithmGetArg(hAlg, "resolution");
        const double res[] = {60, 60};
        GDALAlgorithmArgSetAsDoubleList(hArg, 2, res);
        GDALAlgorithmArgRelease(hArg);
    }

    int ret = 0;
    if( GDALAlgorithmRun(hAlg, NULL, NULL) )
    {
        GDALAlgorithmArgH hArg = GDALAlgorithmGetArg(hAlg, "output");
        GDALArgDatasetValueH hVal = GDALAlgorithmArgGetAsDatasetValue(hArg);
        GDALDatasetH hDS = GDALArgDatasetValueGetDatasetRef(hVal);
        printf("width=%d, height=%d\n", GDALGetRasterXSize(hDS),
↪GDALGetRasterYSize(hDS));
        GDALAlgorithmArgRelease(hArg);
    }
    else
    {
        fprintf(stderr, "failure\n");
        ret = 1;
    }
    GDALAlgorithmFinalize(hAlg);
    GDALAlgorithmRelease(hAlg);
    return ret;
}
```

5.1.1.6 How to use gdal CLI algorithms from C++

Added in version 3.12.

gdal CLI algorithms are available as *GDALAlgorithm* instances, and the include file to use is gdalalgorithm.h.

The first step is to get the instance of the GDALGlobalAlgorithmRegistry with *GDALGlobalAlgorithmRegistry::GetSingleton()* and then call *GDALAlgorithmRegistry::Instantiate()* with the path of the algorithm.

For example:

```
auto &singleton = GDALGlobalAlgorithmRegistry::GetSingleton();
GDALAlgorithm *algPtr = singleton.Instantiate("raster", "reproject");
if (!algPtr)
{
    std::cout << "cannot instantiate algorithm" << std::endl;
    return 1;
}
GDALAlgorithm &alg = *algPtr;
```

Arguments can be queried and set through *GDALAlgorithm::operator[]()*.

For example:

```
alg["input"] = "byte.tif";
alg["output"] = "out.tif";
alg["dst-crs"] = "EPSG:26711";
alg["resampling"] = "cubic";
alg["resolution"] = std::vector<double>{60, 60};
alg["overwrite"] = true;
```

Execution of the algorithm is performed by *GDALAlgorithm::Run()*, with an optional progress function. Proper closing of the output dataset must be performed with *GDALAlgorithm::Finalize()*

For example:

```
if (alg.Run() && alg.Finalize())
{
    std::cout << "success" << std::endl;
    return 0;
}
else
{
    std::cout << "failure" << std::endl;
    return 1;
}
```

When outputting to a *MEM -- In Memory datasets* dataset, you typically want to get the output dataset with:

```
GDALDataset *poDS = alg["output"].Get<GDALArgDatasetValue>().GetDatasetRef();
```

Putting all things together:

```
#include "gdal.h"
#include "gdalalgorithm.h"
#include "gdal_dataset.h"
```

(continues on next page)

(continued from previous page)

```
#include <iostream>

int main()
{
    GDALAllRegister();
    auto& singleton = GDALGlobalAlgorithmRegistry::GetSingleton();
    GDALAlgorithm *algPtr = singleton.Instantiate("raster", "reproject");
    if( !algPtr )
    {
        std::cout << "cannot instantiate algorithm" << std::endl;
        return 1;
    }
    GDALAlgorithm& alg = *algPtr;
    alg["input"] = "byte.tif";
    alg["output-format"] = "MEM";
    alg["dst-crs"] = "EPSG:26711";
    alg["resampling"] = "cubic";
    alg["resolution"] = std::vector<double>{60, 60};
    if( alg.Run() )
    {
        GDALDataset *poDS = alg["output"].Get<GDALArgDatasetValue>().GetDatasetRef();
        std::cout << "width=" << poDS->GetRasterXSize() << std::endl;
        std::cout << "height=" << poDS->GetRasterYSize() << std::endl;
        alg.Finalize();
        return 0;
    }
    else
    {
        std::cout << "failure" << std::endl;
        return 1;
    }
}
```

5.1.1.7 How to use `gdal` CLI algorithms from Python

Principles

`gdal` CLI algorithms are available as *`osgeo.gdal.Algorithm`* instances.

A convenient way to access an algorithm and run it is to use the *`osgeo.gdal.Run()`* function.

Run(**alg*, *arguments={}*, *progress=None*, ***kwargs*)

Run a GDAL algorithm and return it.

Added in version 3.11.

Parameters

- **alg** (*str, list[str], tuple[str],* `Algorithm`) -- Path to the algorithm or algorithm instance itself. For example "raster info", or ["raster", "info"] or "raster", "info".
- **arguments** (*dict*) -- Input arguments of the algorithm. For example {"format": "json", "input": "byte.tif"}

- **progress** (*callable*) -- Progress function whose arguments are a progress ratio, a string and a user data
- **kwargs** -- Instead of using the `arguments` parameter, it is possible to pass algorithm arguments directly as named parameters of gdal.Run(). If the named argument has dash characters in it, the corresponding parameter must replace them with an underscore character. For example `output_crs` as a a parameter of gdal.Run(), instead of `output-crs` which is the name to use on the command line.

Return type
a *osgeo.gdal.Algorithm* instance

If you do not need to access output value(s) of the algorithm, you can call `Run` directly: `gdal.Run(["raster", "convert"], input="in.tif", output="out.tif")`

The name of algorithm arguments are the long names as documented in the documentation page of each algorithm. They can also be obtained with *osgeo.gdal.Algorithm.GetArgNames()*.

```
>>> gdal.Algorithm("raster", "convert").GetArgNames()
['help', 'help-doc', 'version', 'json-usage', 'drivers', 'config', 'progress', 'output-
↪format', 'open-option', 'input-format', 'input', 'output', 'creation-option',
↪'overwrite', 'append']
```

For a command such as *gdal raster info* that returns a JSON output, you can get the return value of *osgeo.gdal.Run()* and call the *osgeo.gdal.Algorithm.Output()* method.

```
alg = gdal.Run("raster", "info", input="byte.tif")
info_as_dict = alg.Output()
```

If the return value is a dataset, *osgeo.gdal.Run()* can be used within a context manager, in which case *osgeo.gdal.Algorithm.Finalize()* will be called at the exit of the context manager.

```
with gdal.Run("raster reproject", input=src_ds, output_format="MEM",
              dst_crs="EPSG:4326") as alg:
    values = alg.Output().ReadAsArray()
```

When not using a context manager, *osgeo.gdal.Algorithm.Finalize()* can be called directly to release the algorithm's references to the output dataset and free associated resources. If a variable still references the dataset, it will not be closed and may still be accessed:

```
>>> alg = gdal.Run("raster reproject", input=src_ds, output_format="MEM",
               dst_crs="EPSG:4326")
>>> out_ds = alg.Output()
>>> print(out_ds.GetRefCount())
2
>>> alg.Finalize()
>>> print(out_ds.GetRefCount())
1
>>> alg.Output().ReadAsArray() # no longer available from the algorithm
AttributeError: 'NoneType' object has no attribute 'ReadAsMaskedArray'
>>> out_ds.ReadAsArray() # still accessible via the existing reference
array([[-9999., -9999., -9999., ...,
```

gdal.alg module

Added in version 3.12.

The gdal.alg module is also available with submodules and functions reflecting the hierarchy of algorithms. Functions return an *osgeo.gdal.Algorithm* instance similarly to *osgeo.gdal.Run()*

The above example running "gdal raster convert" can also be rewritten as:

```
>>> from osgeo import gdal
>>> gdal.alg.raster.convert(input="in.tif", output="out.tif")
```

The documentation of the function lists argument names, types and semantics:

```
>>> from osgeo import gdal
>>> help(gdal.alg.raster.convert)

    Help on function convert:

    convert(input: Union[List[osgeo.gdal.Dataset], List[str], List[os.PathLike[str]]],␣
↪output: Union[osgeo.gdal.Dataset, str, os.PathLike[str]], input_format:␣
↪Union[List[str], str, NoneType] = None, open_option: Union[List[str], str, NoneType] =␣
↪None, output_format: Optional[str] = None, creation_option: Union[List[str], str,␣
↪NoneType] = None, overwrite: Optional[bool] = None, append: Optional[bool] = None)
        Convert a raster dataset.

        Consult https://gdal.org/programs/gdal_raster_convert.html for more details.

        Parameters
        ----------
        input: Union[List[gdal.Dataset], List[str], List[os.PathLike[str]]]
            Input raster datasets
        output: Union[gdal.Dataset, str, os.PathLike[str]]
            Output raster dataset
        input_format: Optional[Union[List[str], str]]=None
            Input formats
        open_option: Optional[Union[List[str], dict, str]]=None
            Open options
        output_format: Optional[str]=None
            Output format ("GDALG" allowed)
        creation_option: Optional[Union[List[str], dict, str]]=None
            Creation option
        overwrite: Optional[bool]=None
            Whether overwriting existing output is allowed
        append: Optional[bool]=None
            Append as a subdataset to existing output

        Output parameters
        -----------------
        output: gdal.ArgDatasetValue
            Output raster dataset
```

Raster commands examples

Example 1: Getting information on a raster dataset as JSON

```
from osgeo import gdal

gdal.UseExceptions()
info_as_dict = gdal.alg.raster.info(input="byte.tif").Output()
```

Example 2: Converting a georeferenced netCDF file to cloud-optimized GeoTIFF

```
from osgeo import gdal

gdal.UseExceptions()
gdal.alg.raster.convert(input="in.tif", output="out.tif", output_format="COG",␣
↪overwrite=True)
```

or

```
from osgeo import gdal

gdal.UseExceptions()
gdal.Run("raster", "convert", input="in.tif", output="out.tif",
         output_format="COG", overwrite=True)
```

or

```
from osgeo import gdal

gdal.UseExceptions()
gdal.Run(["raster", "convert"], {"input": "in.tif", "output": "out.tif", "output-format
↪": "COG", "overwrite": True})
```

Example 3: Reprojecting a GeoTIFF file to a Deflate-compressed tiled GeoTIFF file

```
from osgeo import gdal

gdal.UseExceptions()
gdal.alg.raster.reproject(
          input="in.tif", output="out.tif",
          dst_crs="EPSG:4326",
          creation_options={ "TILED": "YES", "COMPRESS": "DEFLATE"})
```

Example 4: Reprojecting a (possibly in-memory) dataset to a in-memory dataset

```
from osgeo import gdal

gdal.UseExceptions()
with gdal.alg.raster.reproject(input=src_ds, output_format="MEM",
               dst_crs="EPSG:4326") as alg:
    values = alg.Output().ReadAsArray()
```

Vector commands examples

Example 5: Getting information on a vector dataset as JSON

```
from osgeo import gdal

gdal.UseExceptions()
info_as_dict = gdal.alg.vector.info(input="poly.gpkg").Output()
```

Example 6: Converting a shapefile to a GeoPackage

```
from osgeo import gdal

gdal.UseExceptions()
gdal.alg.vector.convert(input="in.shp", output="out.gpkg", overwrite=True)
```

Pipeline examples

Example 7: Perform raster reprojection and gets the result as a streamed dataset.

```
from osgeo import gdal

gdal.UseExceptions()
with gdal.alg.pipeline(pipeline="read byte.tif ! reproject --output-crs EPSG:4326 --
↪resampling cubic") as alg:
    ds = alg.Output()
    # do something with the dataset
```

5.1.1.8 .gdalg files to replay serialized `gdal` commands

A subset of subcommands of **`gdal`** support generating on-the-fly / streamed raster of vector datasets. They are typically saved to a "real" output dataset, but it is also possible to save them in a JSON file of extension `.gdalg.json`, that can be read by the *GDALG: GDAL Streamed Algorithm* driver or *GDALG: GDAL Streamed Algorithm* driver to apply the saved processing on-the-fly and use the resulting dataset as a regular input dataset for *`GDALOpenEx()`*, or anywhere in GDAL API or command line utilities where a raster input dataset is expected. GDALG files are conceptually close to *VRT (Virtual) files*, although the implementation is substantially different.

> **Note**
>
> GDALG is the contraction of GDAL and ALGorithm.

In-process stream execution

For algorithms that support GDALG output, it is also possible to use the `stream` output format to indicate that a raster or vector streamed dataset must be returned.

For example the following snippet, runs that "gdal vector set-type" algorithm on a source dataset and iterates over features from the returned streamed dataset.

```
from osgeo import gdal
gdal.UseExceptions()
```

(continues on next page)

(continued from previous page)

```
alg = gdal.GetGlobalAlgorithmRegistry()["vector"]["geom"]["set-type"]
alg["input"] = src_ds
alg["output"] = ""
alg["output-format"] = "stream"
alg["geometry-type"] = "LINESTRING Z"

alg.Run()

out_ds = alg["output"].GetDataset()
out_lyr = out_ds.GetLayer(0)
for f in our_lyr:
    f.DumpReadable()
```

Examples

Example 1: Serialize the command of a reprojection of a GeoPackage file in a GDALG file, and later read it

```
    $ gdal vector pipeline ! read in.gpkg ! reproject --output-crs=EPSG:32632 ! write in_
↪epsg_32632.gdalg.json --overwrite
    $ gdal vector info in_epsg_32632.gdalg.json

The content of :file:`in_epsg_32632.gdalg.json` is:

.. code-block:: json

    {
        "type": "gdal_streamed_alg",
        "command_line": "gdal vector pipeline ! read in.gpkg ! reproject --output-
↪crs=EPSG:32632"
    }
```

5.1.2 Commands working with raster or vector inputs

5.1.2.1 gdal info

Added in version 3.11.

Acts as a shortcut for *gdal raster info* or *gdal vector info* depending on the nature of the specified dataset.

Synopsis

```
Usage: gdal info [OPTIONS] <INPUT>

Return information on a dataset (shortcut for 'gdal raster info' or 'gdal vector info').

Positional arguments:
  -i, --dataset, --input <INPUT>                        Input raster, vector or␣
↪multidimensional raster dataset [required]

Common Options:
```

(continues on next page)

(continued from previous page)

```
  -h, --help                                          Display help message and exit
  --json-usage                                        Display usage as JSON document␣
↪and exit
  --config <KEY>=<VALUE>                              Configuration option [may be␣
↪repeated]

Options:
  -f, --of, --format, --output-format <OUTPUT-FORMAT>  Output format. OUTPUT-
↪FORMAT=json|text

For all options, run 'gdal raster info --help' or 'gdal vector info --help'
```

Return status code

The program returns status code 0 in case of success, and non-zero in case of error (non-blocking errors emitted as warnings are considered as a successful execution).

Examples

Example 1: Getting information on the file utmsmall.tif (with text output)

```
$ gdal info utmsmall.tif
Driver: GTiff/GeoTIFF
Files: utmsmall.tif
Size is 100, 100
Coordinate Reference System:
  - name: NAD27 / UTM zone 11N
  - ID: EPSG:26711
  - type: Projected
  - projection type: Transverse Mercator
  - units: metre
Data axis to CRS axis mapping: 1,2
Origin = (440720.000000000000000,3751320.000000000000000)
Pixel Size = (60.000000000000000,-60.000000000000000)
Metadata:
  AREA_OR_POINT=Area
Image Structure Metadata:
  INTERLEAVE=BAND
Corner Coordinates:
Upper Left  (  440720.000, 3751320.000) (117d38'28.21"W, 33d54' 8.47"N)
Lower Left  (  440720.000, 3745320.000) (117d38'26.75"W, 33d50'53.66"N)
Upper Right (  446720.000, 3751320.000) (117d34'34.59"W, 33d54' 9.62"N)
Lower Right (  446720.000, 3745320.000) (117d34'33.28"W, 33d50'54.82"N)
Center      (  443720.000, 3748320.000) (117d36'30.71"W, 33d52'31.66"N)
Band 1 Block=100x81 Type=Byte, ColorInterp=Gray
```

Example 2: Getting information on the file poly.gpkg (with JSON output), listing all features

```
$ gdal vector info --format=JSON --features poly.gpkg
{
  "description":"poly.gpkg",
```

(continues on next page)

(continued from previous page)

Example 3: Getting the list of all drivers (with JSON output)

```
$ gdal --drivers
```

5.1.2.2 gdal convert

Added in version 3.11.

Acts as a shortcut for *gdal raster convert* or *gdal vector convert* depending on the nature of the specified dataset.

Synopsis

```
Usage: gdal convert [OPTIONS] <INPUT> <OUTPUT>

Convert a dataset (shortcut for 'gdal raster convert' or 'gdal vector convert').

Positional arguments:
  -i, --input <INPUT>                                  Input raster, vector or␣
↪multidimensional raster dataset [required]
  -o, --output <OUTPUT>                                Output raster, vector or␣
↪multidimensional raster dataset (created by algorithm) [required]

Common Options:
  -h, --help                                           Display help message and exit
  --json-usage                                         Display usage as JSON document␣
↪and exit
  --config <KEY>=<VALUE>                               Configuration option [may be␣
↪repeated]
  -q, --quiet                                          Quiet mode (no progress bar or␣
↪warning message) [not available in pipelines]

Options:
  -f, --of, --format, --output-format <OUTPUT-FORMAT>  Output format

For all options, run 'gdal raster convert --help' or 'gdal vector convert --help'
```

Return status code

The program returns status code 0 in case of success, and non-zero in case of error (non-blocking errors emitted as warnings are considered as a successful execution).

Examples

Example 1: Converting file utm.tif to GeoPackage raster

```
$ gdal convert utm.tif utm.gpkg
```

5.1.2.3 gdal pipeline

Added in version 3.12.

Description

gdal pipeline execute a pipeline, taking a raster or input dataset, execute steps and finally writing a raster or vector dataset.

Most steps proceed in on-demand evaluation of raster blocks or features, unless otherwise stated in their documentation, without "materializing" the resulting dataset of the operation of each step. It may be desirable sometimes for performance purposes to proceed to materializing an intermediate dataset to disk using *gdal raster materialize* or *gdal vector materialize*.

Synopsis

```
Usage: gdal pipeline [OPTIONS] <PIPELINE>

Process a dataset applying several steps.

Positional arguments:

Common Options:
  -h, --help                        Display help message and exit
  --json-usage                      Display usage as JSON document and exit
  --config <KEY>=<VALUE>            Configuration option [may be repeated]
  -q, --quiet                       Quiet mode (no progress bar or warning message) [not␣
↪available in pipelines]

Advanced Options:
  --<user-provided-option>=<value>  Argument provided by user

<PIPELINE> is of the form: read|calc|concat|create|mosaic|stack [READ-OPTIONS] ( ! <STEP-
↪NAME> [STEP-OPTIONS] )* ! write!info!tile [WRITE-OPTIONS]
```

A pipeline chains several steps, separated with the `!` (exclamation mark) character. Including a `!` between `gdal pipeline` and the first step is optional. The first step must be `read`, `calc`, `concat`, `mosaic` or `stack`, and the last one `export-schema`, `info`, `tile` or `write`. Each step has its own positional or non-positional arguments. Apart from `read`, `calc`, `concat`, `mosaic`, `stack`, `info`, `tile`, `partition` and `write`, all other steps can potentially be used several times in a pipeline.

Example 1: Compute the footprint of a raster and apply a buffer on the footprint

```
$ gdal pipeline ! read in.tif ! footprint ! buffer 20 ! write out.gpkg --overwrite
```

Steps

For steps that have both *raster* data type as input and output, consult *gdal raster pipeline*. For steps that have both *vector* data type as input and output, consult *gdal vector pipeline*.

The table below lists steps that convert between raster and vector data.

Step	Direction
contour	Raster → Vector
footprint	Raster → Vector
pixel-info	Raster → Vector
polygonize	Raster → Vector
grid	Vector → Raster
rasterize	Vector → Raster
tee	Vector → Raster

contour

```
* contour [OPTIONS]
-------------------

Creates a vector contour from a raster elevation model (DEM).

Options:
  --output-layer <OUTPUT-LAYER>              Output layer name
  -b, --band <BAND>                          Input band (1-based index) (default: 1)
  --elevation-name <ELEVATION-NAME>          Name of the elevation field
  --min-name <MIN-NAME>                      Name of the minimum elevation field
  --max-name <MAX-NAME>                      Name of the maximum elevation field
  --3d                                       Force production of 3D vectors instead of 2D
  --input-nodata <INPUT-NODATA>              Input pixel value to treat as 'nodata'
  --interval <INTERVAL>                      Elevation interval between contours
                                             Mutually exclusive with --levels, --exp-base
  --levels <LEVELS>                          List of contour levels [may be repeated]
                                             Mutually exclusive with --interval, --exp-
↪base
  -e, --exp-base <EXP-BASE>                  Base for exponential contour level␣
↪generation
                                             Mutually exclusive with --interval, --levels
  --off, --offset <OFFSET>                   Offset to apply to contour levels
  -p, --polygonize                           Create polygons instead of lines
  --group-transactions <GROUP-TRANSACTIONS>  Group n features per transaction (default␣
↪100 000)
```

Details for options can be found in *gdal raster contour*.

footprint

```
* footprint [OPTIONS]
---------------------

Compute the footprint of a raster dataset.

Options:
  --output-layer <OUTPUT-LAYER>              Output layer name (default: footprint)
  -b, --band <BAND>                          Input band(s) (1-based index) [may be␣
↪repeated]
  --combine-bands <COMBINE-BANDS>            Defines how the mask bands of the selected␣
```

(continues on next page)

(continued from previous page)

```
↪bands are combined to generate a single mask band, before being vectorized.. COMBINE-
↪BANDS=union|intersection (default: union)
  --overview <OVERVIEW>                      Which overview level of source file must be␣
↪used
                                             Mutually exclusive with --input-nodata
  --input-nodata <INPUT-NODATA>              Set nodata values for input bands. [1..␣
↪values]
                                             Mutually exclusive with --overview
  --coordinate-system <COORDINATE-SYSTEM>    Target coordinate system. COORDINATE-
↪SYSTEM=georeferenced|pixel
  --output-crs <OUTPUT-CRS>                  Output CRS
  --split-multipolygons                      Whether to split multipolygons as several␣
↪features each with one single polygon
  --convex-hull                              Whether to compute the convex hull of the␣
↪footprint
  --densify-distance <DENSIFY-DISTANCE>      Maximum distance between 2 consecutive␣
↪points of the output geometry.
  --simplify-tolerance <SIMPLIFY-TOLERANCE>  Tolerance used to merge consecutive points␣
↪of the output geometry.
  --min-ring-area <MIN-RING-AREA>            Minimum value for the area of a ring
  --max-points <MAX-POINTS>                  Maximum number of points of each output␣
↪geometry (default: 100)
  --location-field <LOCATION-FIELD>          Name of the field where the path of the␣
↪input dataset will be stored. (default: location)
                                             Mutually exclusive with --no-location-field
  --no-location-field                        Disable creating a field with the path of␣
↪the input dataset
                                             Mutually exclusive with --location-field
  --absolute-path                            Whether the path to the input dataset␣
↪should be stored as an absolute path
```

Details for options can be found in *gdal raster footprint*.

grid

```
* grid <COMMAND> [OPTIONS]
--------------------------

where <COMMAND> is one of:
  - average:                 Create a regular grid from scattered points using moving␣
↪average interpolation.
  - average-distance:        Create a regular grid from scattered points using the␣
↪average distance between the grid node (center of the search ellipse) and all of the␣
↪data points in the search ellipse.
  - average-distance-points: Create a regular grid from scattered points using the␣
↪average distance between the data points in the search ellipse.
  - count:                   Create a regular grid from scattered points using the␣
↪number of points in the search ellipse.
  - invdist:                 Create a regular grid from scattered points using weighted␣
↪inverse distance interpolation.
  - invdistnn:               Create a regular grid from scattered points using weighted␣
↪inverse distance interpolation nearest neighbour.
```

(continues on next page)

(continued from previous page)

```
  - linear:                  Create a regular grid from scattered points using linear/
↪barycentric interpolation.
  - maximum:                 Create a regular grid from scattered points using the␣
↪maximum value in the search ellipse.
  - minimum:                 Create a regular grid from scattered points using the␣
↪minimum value in the search ellipse.
  - nearest:                 Create a regular grid from scattered points using nearest␣
↪neighbor interpolation.
  - range:                   Create a regular grid from scattered points using the␣
↪difference between the minimum and maximum values in the search ellipse.
```

Details for options can be found in *gdal vector grid*.

pixel-info

```
* pixel-info [OPTIONS] <INPUT> [<POSITION-DATASET>]
--------------------------------------------------

Return information on a pixel of a raster dataset.

Positional arguments:
  -i, --dataset, --input <INPUT>                Input raster datasets [required]
  --position-dataset <POSITION-DATASET>         Vector dataset with coordinates
                                                Mutually exclusive with --position

Options:
  -l, --layer, --input-layer <INPUT-LAYER>      Input layer name
  -b, --band <BAND>                             Input band(s) (1-based index) [may be␣
↪repeated]
  --overview <OVERVIEW>                         Which overview level of source file must␣
↪be used
  -p, --pos, --position <column,line> or <X,Y>  Pixel position [may be repeated]
                                                Mutually exclusive with --position-
↪dataset
  --position-crs <POSITION-CRS>                 CRS of position (default is 'pixel' if
↪'position-dataset' not specified)
  -r, --resampling <RESAMPLING>                 Resampling algorithm for interpolation.␣
↪RESAMPLING=nearest|bilinear|cubic|cubicspline (default: nearest)
  --promote-pixel-value-to-z                    Whether to set the pixel value as Z␣
↪component of GeoJSON geometry
  --include-field <INCLUDE-FIELD>               Fields from coordinate dataset to␣
↪include in output (special values: ALL and NONE) (default: ALL) [may be repeated]
```

Details for options can be found in *gdal raster pixel-info*.

polygonize

```
* polygonize [OPTIONS]
----------------------

Create a polygon feature dataset from a raster band.
```

(continues on next page)

(continued from previous page)

```
Options:
  --output-layer <OUTPUT-LAYER>      Output layer name
  -b, --band <BAND>                  Input band (1-based index) (default: 1)
  --attribute-name <ATTRIBUTE-NAME>  Name of the field with the pixel value (default: DN)
  -c, --connect-diagonal-pixels      Consider diagonal pixels as connected
```

Details for options can be found in *gdal raster polygonize*.

rasterize

```
* rasterize [OPTIONS]
---------------------

Burns vector geometries into a raster.

Options:
  -b, --band <BAND>                                          The band(s) to burn values␣
↪into (1-based index) [may be repeated]
  --invert                                                   Invert the rasterization
  --all-touched                                              Enables the ALL_TOUCHED␣
↪rasterization option
  --burn <BURN>                                              Burn value [may be repeated]
  -a, --attribute-name <ATTRIBUTE-NAME>                      Attribute name
  --3d                                                       Indicates that a burn value␣
↪should be extracted from the Z values of the feature
  -l, --input-layer <INPUT-LAYER>                            Input layer name
                                                             Mutually exclusive with --sql
  --where <WHERE>                                            SQL where clause
  --sql <SQL>                                                SQL select statement
                                                             Mutually exclusive with --
↪input-layer
  --dialect <DIALECT>                                        SQL dialect
  --nodata <NODATA>                                          Assign a specified nodata␣
↪value to output bands
  --init <INIT>                                              Pre-initialize output bands␣
↪with specified value [may be repeated]
  --crs <CRS>                                                Override the projection for␣
↪the output file
  --transformer-option <NAME>=<VALUE>                        Set a transformer option␣
↪suitable to pass to GDALCreateGenImgProjTransformer2 [may be repeated]
  --extent <xmin>,<ymin>,<xmax>,<ymax>                       Set the target georeferenced␣
↪extent [4 values]
  --resolution <xres>,<yres>                                 Set the target resolution [2␣
↪values]
                                                             Mutually exclusive with --size
  --tap, --target-aligned-pixels                             (target aligned pixels) Align␣
↪the coordinates of the extent of the output file to the values of the resolution
                                                             Depends on --resolution
  --size <xsize>,<ysize>                                     Set the target size in pixels␣
↪and lines [2 values]
                                                             Mutually exclusive with --
```

(continues on next page)

(continued from previous page)

```
↪resolution
  --ot, --datatype, --output-data-type <OUTPUT-DATA-TYPE>  Output data type. OUTPUT-DATA-
↪TYPE=UInt8|Int8|UInt16|Int16|UInt32|Int32|UInt64|Int64|CInt16|CInt32|Float16|Float32|Float64|CFloat32
  --optimization <OPTIMIZATION>                            Force the algorithm used␣
↪(results are identical). OPTIMIZATION=AUTO|RASTER|VECTOR (default: AUTO)
```

Details for options can be found in *gdal vector rasterize*.

tee

```
* tee [OPTIONS] [<PIPELINE>...]
------------------------------

Pipes the input into the output stream and side nested pipelines.

Positional arguments:
  --tee-pipeline <PIPELINE>  Nested pipeline [1.. values]
```

Details for options can be found in *Output nested pipeline*.

GDALG output (on-the-fly / streamed dataset)

A pipeline can be serialized as a JSON file using the `GDALG` output format. The resulting file can then be opened as a dataset using the *GDALG: GDAL Streamed Algorithm* or *GDALG: GDAL Streamed Algorithm* driver, and apply the specified pipeline in a on-the-fly / streamed way.

The `command_line` member of the JSON file should nominally be the whole command line without the final `write` step, and is what is generated by `gdal pipeline ! .... ! write out.gdalg.json`.

```
{
    "type": "gdal_streamed_alg",
    "command_line": "gdal pipeline ! read in.tif ! footprint ! buffer 20"
}
```

The final `write` step can be added but if so it must explicitly specify the `stream` output format and a non-significant output dataset name.

```
{
    "type": "gdal_streamed_alg",
    "command_line": "gdal pipeline ! read in.tif ! footprint ! buffer 20 ! write --
↪output-format=streamed streamed_dataset"
}
```

Substitutions

It is also possible to use **`gdal pipeline`** to use a pipeline already serialized in a `.gdalg.json` file, and customize its existing steps, typically changing an input filename, specifying an output filename, or adding/modifying arguments of steps.

The syntax is:

```
gdal pipeline <filename.gdalg.json> --<step-name>.<arg-name>=value
```

When specifying an existing argument of a step of a pipeline, the value from the pipeline is overridden by the one specified on the **gdal pipeline** command line.

Let's imagine we have a `raster_reproject.gdalg.json` with the following content:

```
{
    "type": "gdal_streamed_alg",
    "command_line": "gdal pipeline ! read in.tif ! reproject --output-crs=EPSG:4326 !␣
↪edit --metadata=CHANGES=reprojected"
}
```

It is possible to run it with the following command line, overriding the `input` argument of the `read` step, and implicitly adding a final `write` step with an `output` argument.

```
$ gdal pipeline raster_reproject.gdalg.json --read.input=other_input.tif --write.
↪output=out.tif
```

When there is no ambiguity, it is also possible to omit the step name, and just specify the argument name (if there is an ambiguity, **gdal pipeline** will emit an error, so this is safe to do):

```
$ gdal pipeline raster_reproject.gdalg.json --input=other_input.tif --output=out.tif --
↪co COMPRESS=LZW --overwrite
```

When a step appears several times in the pipeline, it must specified as `<step-name>[<idx>]`, where `<idx>` is a zero-based index.

For example, given:

```
{
    "type": "gdal_streamed_alg",
    "command_line": "gdal pipeline ! read in.tif ! edit --metadata=before=value !␣
↪reproject --output-crs=EPSG:4326 ! edit --metadata=CHANGES=reprojected"
}
```

the following command line may be used:

```
$ gdal pipeline raster_reproject.gdalg.json --edit[0].metadata=before=modified --
↪output=out.tif
```

Execution of pipelines and argument substitutions can also be done in Python with:

```
gdal.Run("pipeline", pipeline="raster_reproject.gdalg.json", output="out.tif", arguments=
↪{"edit[0].metadata": "before=modified"})
```

Placeholder dataset name `_PIPE_`

Added in version 3.13.

By default, in a pipeline step that accepts multiple input dataset arguments, the first positional argument, `input`, is implicitly set to the output dataset from the previous step. In some cases, it might be desirable to pipe the output dataset from the previous step into one of the other input dataset arguments instead.

This can be achieved by using the placeholder dataset name `_PIPE_` (PIPE with leading and trailing underscore character) as the value for the alternate dataset argument, while explicitly specifying the input positional dataset argument.

Example 2: Summarize mean elevation within 200m of points of interest

```
gdal pipeline read points.geojson ! buffer 200 ! \
    zonal-stats \
      --input dem.tif
      --zones _PIPE_ \
      --stat mean ! \
    write \
      --output-format CSV \
      --output /vsistdout/
```

It is also possible to achieve the same result by using a input nested pipeline as described below.

Nested pipeline

It is possible to create "nested pipelines", i.e. pipelines inside pipelines.

A nested pipeline is delimited by square brackets (`[` and `]`) surrounded by a space character.

There are 2 kinds of nested pipelines:

- input nested pipelines: where the result dataset of the nested pipeline is used as the input dataset for an argument of the main pipeline.
- output nested pipelines: where the output of a step of the main pipeline is used as the input of the nested pipeline in a following step. Output nested pipelines can only be used with the `tee` step.

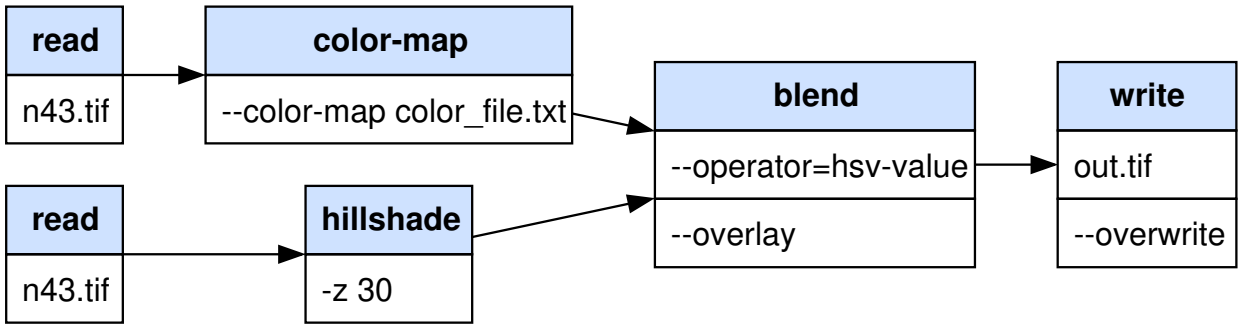
Input nested pipeline

Wherever an input dataset is expected as an auxiliary dataset, it is possible to specify it as the result of a nested pipeline. The content of an input nested pipeline is identical to the outer pipeline, except it must not end with an output-generating step like `info`, `tile` or `write`

Example 3: Combine the output of shaded relief map and hypsometric rendering on a DEM to create a colorized shaded relief map.

```
$ gdal pipeline read n43.tif ! \
                color-map --color-map color_file.txt ! \
                blend --operator=hsv-value --overlay \
                    [ read n43.tif ! hillshade -z 30 ] ! \
                write out.tif --overwrite
```

In the above example, the value of the `overlay` argument of the `blend` step is set as the output of the nested pipeline `read n43.tif ! hillshade -z 30`.



Output nested pipeline

The `tee` step in a pipeline forwards the input dataset as its output, and additionally executes one or several nested pipelines that take this input dataset as input and do other processing to eventually write the output of that processing. The first step of a `tee` output nested pipeline *must* not be `read`, `calc`, `concat`, `mosaic` or `stack`, and its last step *must* be `write` or `tile`. The `tee` operator can be either used in the middle of a pipeline or as its last step.

The below example shows an example where the `tee` operator executes two output nested pipelines.

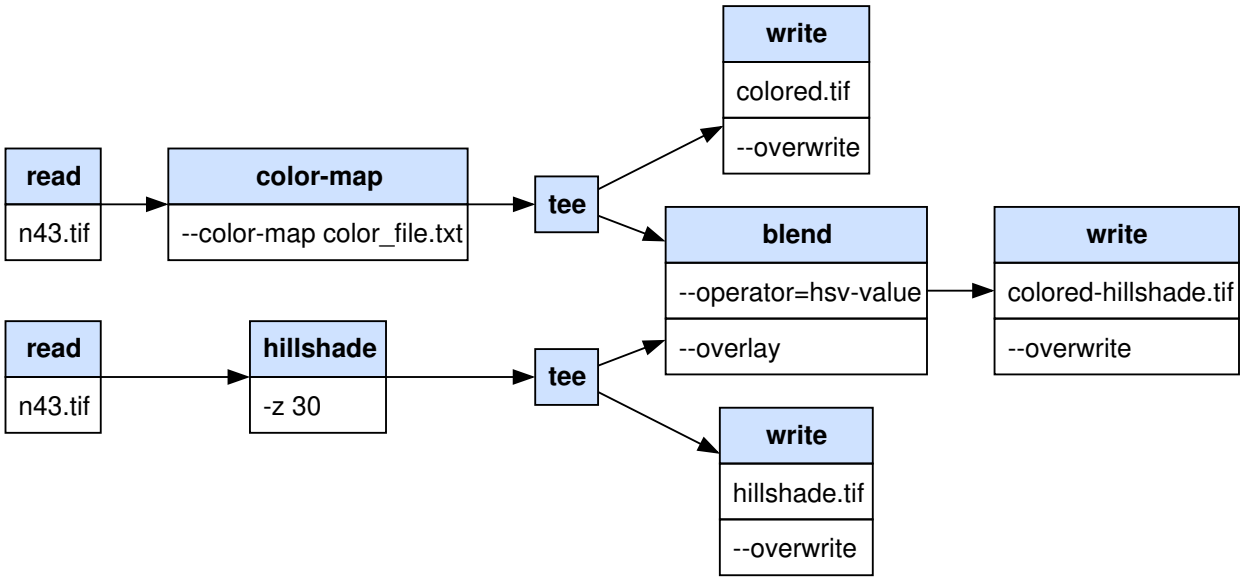
Example 4: Split the content of a "cities" layer according to whether its population is below or above 1 million.

```
$ gdal pipeline read cities.gpkg ! \
        tee [ filter --where "pop < 1e6" ! write small_cities.gpkg ] \
            [ filter --where "pop >= 1e6" ! write big_cities.gpkg ]
```

The below example shows a more complicated use case, including two occurrences of `tee`, with one of them being an output nested pipeline inside an input nested pipeline.

Example 5: Combine the output of shaded relief map and hypsometric rendering on a DEM to create a colorized shaded relief map, and write intermediate hillshade and colorized dataset

```
$ gdal pipeline read n43.tif ! \
                color-map --color-map color_file.txt ! \
                tee [ write colored.tif --overwrite ] ! \
                blend --operator=hsv-value --overlay \
                    [ read n43.tif ! hillshade -z 30  ! tee [ write hillshade.tif --
↪overwrite ] ] ! \
                write colored-hillshade.tif --overwrite
```



Return status code

The program returns status code 0 in case of success, and non-zero in case of error (non-blocking errors emitted as warnings are considered as a successful execution).

Examples

Example 6: Compute the footprint of a raster and apply a buffer on the footprint

```
$ gdal pipeline ! read in.tif ! footprint ! buffer 20 ! write out.gpkg --overwrite
```

Example 7: Rasterize and reproject

```
$ gdal pipeline ! read in.gpkg ! rasterize --size 1000,1000 ! reproject --output-crs␣
↪EPSG:4326 ! write out.tif --overwrite
```

Example 8: Use an existing pipeline that rasterizes and reprojects, but change its input file and target CRS, and specify the output file

```
$ gdal pipeline raster_reproject.gdalg.json --input=my.gpkg --output=out.tif --output-
↪crs=EPSG:32631
```

Example 9: Buffer a line dataset to create a new polygon dataset

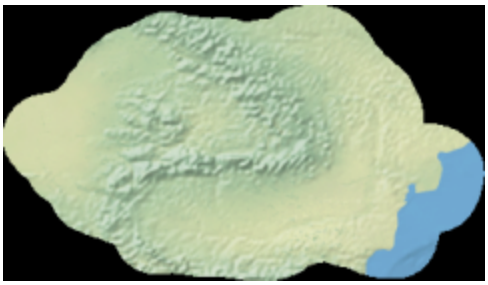
This example uses a `lines.gpkg` dataset containing a single layer named `lines`, with a geometry field named `geom` and an integer attribute named `width`. The value of this attribute is used as the buffer distance for each feature.

```
gdal vector pipeline \
    ! read lines.gpkg \
    ! sql "SELECT fid, ST_Buffer(geom, width) AS geom FROM lines" \
    ! set-geom-type --geometry-type Polygon \
    ! write buffered-lines.gpkg --output-layer=BufferedLines --overwrite --overwrite-
↪layer
```

> **Note**
>
> When creating derived geometries using SQL, avoid using `SELECT *`. Including the original geometry field will result in multiple geometry columns in the output. Instead, explicitly list the required attributes and return a single geometry column.

Example 10: Clip a raster dataset using a nested vector pipeline

This pipeline uses a raster input dataset, and clips it using a buffered geometry coming from a nested vector pipeline. The resulting clipped raster is then resized and written to disk, and shown in the image below.

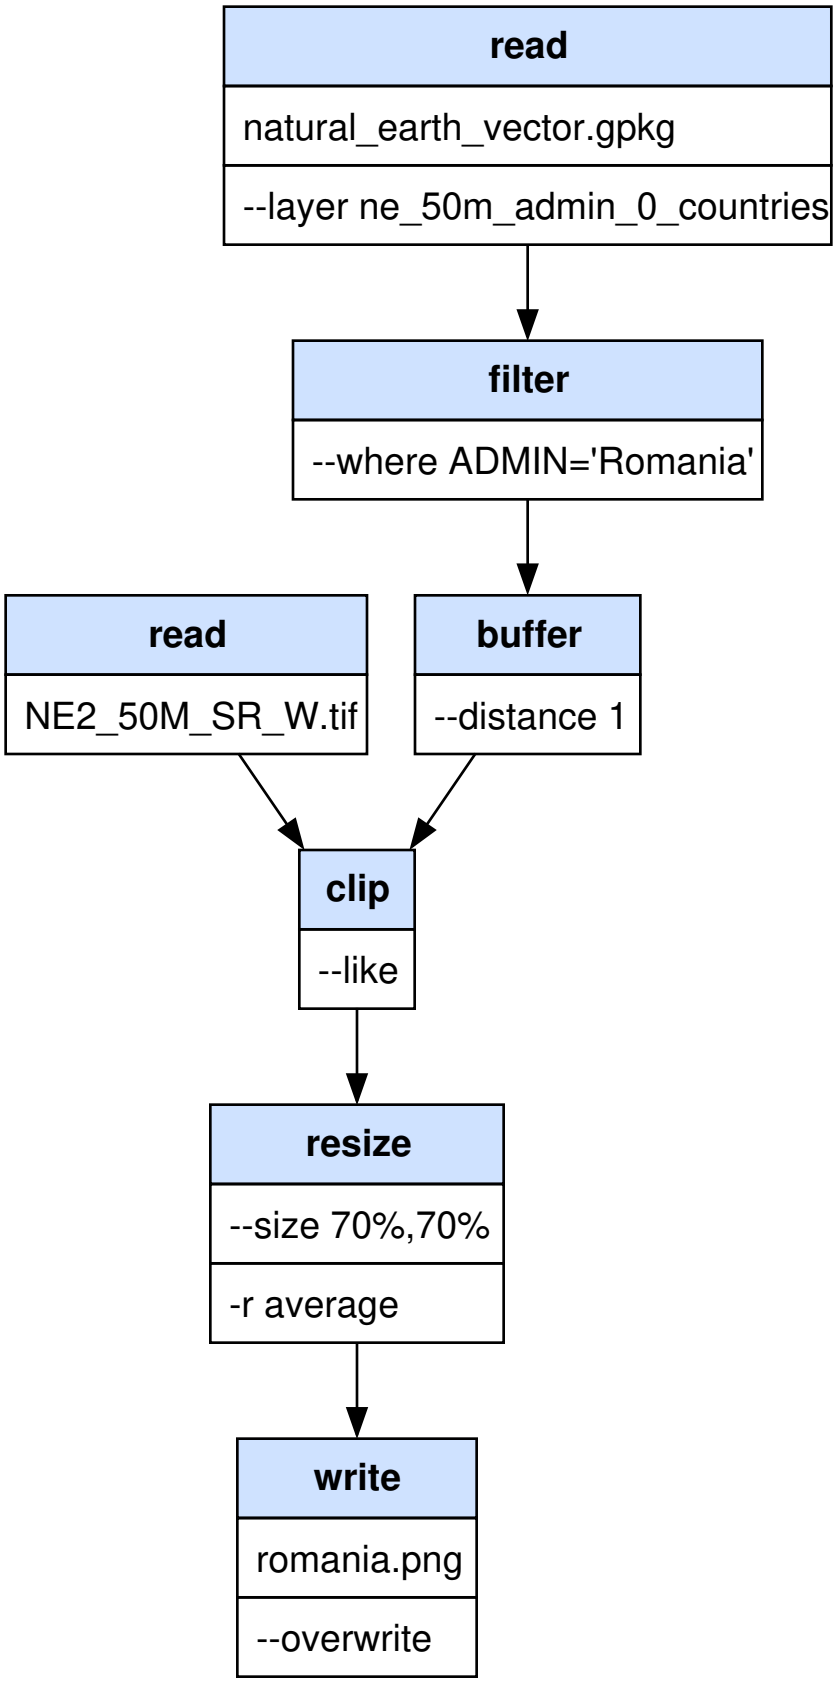


Bash

PowerShell

```
gdal pipeline \
    ! read "NE2_50M_SR_W.tif" \
    ! clip --like [ read natural_earth_vector.gpkg --layer "ne_50m_admin_0_countries" !␣
↪filter --where "ADMIN='Romania'" ! buffer --distance=1 ] \
    ! resize --size=70%,70% -r average \
    ! write romania.png --overwrite
```

```
gdal pipeline `
    ! read "NE2_50M_SR_W.tif" `
    ! clip --like [ read natural_earth_vector.gpkg --layer "ne_50m_admin_0_countries" !␣
↪filter --where "ADMIN='Romania'" ! buffer --distance=1 ] `
    ! resize --size=70%,70% -r average `
    ! write romania.png --overwrite
```



read
natural_earth_vector.gpkg
--layer ne_50m_admin_0_countries
filter
--where ADMIN='Romania'
read
NE2_50M_SR_W.tif
buffer
--distance 1
clip
--like
resize
--size 70%,70%
-r average
write
romania.png
--overwrite

Example 11: Clip a raster dataset with vector features using _PIPE_

This pipeline produces the same result as *Example 10*, but instead of using a nested pipeline for the clipping geometry, it uses the special placeholder dataset name *__PIPE__* to pass the output of the buffering step to `clip`.

Bash

PowerShell

```
gdal pipeline \
  ! read natural_earth_vector.gpkg --layer "ne_50m_admin_0_countries" \
  ! filter --where "ADMIN='Romania'" \
  ! buffer --distance=1 \
  ! clip --input "NE2_50M_SR_W.tif" --like _PIPE_ \
  ! resize --size=70%,70% -r average \
  ! write romania.png --overwrite
```

```
gdal pipeline `
  ! read natural_earth_vector.gpkg --layer "ne_50m_admin_0_countries" `
  ! filter --where "ADMIN='Romania'" `
  ! buffer --distance=1 `
  ! clip --input "NE2_50M_SR_W.tif" --like _PIPE_ `
  ! resize --size=70%,70% -r average `
  ! write romania.png --overwrite
```

5.1.2.4 `gdal external`

Added in version 3.13.

Description

`external` can be used as a step (in any position) in a generic, raster or vector pipeline to execute an arbitrary external process.

For security reasons (in particular when embedded in GDALG pipelines), its execution requires the `GDAL_ENABLE_EXTERNAL` configuration option to be set to YES.

The command line executed by this step can accept the following optional placeholders:

- `<INPUT>` that is replaced by the name of a temporary file, generated from the input of the previous step. The format used by default to materialize that file is GeoTIFF for raster and GeoPackage for vector, unless the *`--input-format`* is specified.
- `<OUTPUT>` that is replaced by the name of a temporary file, generated by the external command. The format used by default to materialize that file is GeoTIFF for raster and GeoPackage for vector, unless the *`--output-format`* is specified. Upon the completion of the external command, the temporary file is opened, and passed to the next step of the pipeline.
- `<INPUT-OUTPUT>` that is used for an external program that updates in place a dataset. The format used by default to materialize that file is GeoTIFF for raster and GeoPackage for vector, unless the *`--input-format`* is specified.

The directory where temporary files are created can be set with the *`CPL_TMPDIR`* configuration option.

If no `<OUTPUT>` or `<INPUT-OUTPUT>` placeholder is specified, the output of the step before `external` is reused as the output of `external`.

Synopsis

```
* external [OPTIONS] <COMMAND>
-----------------------------

Execute an external program as a step of a pipeline

Positional arguments:
  --command <COMMAND>                                External command, optionally with
↪<INPUT> and/or <OUTPUT> or <INPUT-OUTPUT> placeholders [required]

Options:
  -f, --of, --format, --output-format <OUTPUT-FORMAT>  Output format

Advanced Options:
  --if, --input-format <INPUT-FORMAT>                  Input formats
```

Program-Specific Options

--command <COMMAND>

External command, optionally with <INPUT> and/or <OUTPUT> or <INPUT-OUTPUT> placeholders [required]

Standard Options

--if, --input-format <format>

Format/driver name to be attempted to open the input file(s). It is generally not necessary to specify it, but it can be used to skip automatic driver detection, when it fails to select the appropriate driver. This option can be repeated several times to specify several candidate drivers. Note that it does not force those drivers to open the dataset. In particular, some drivers have requirements on file extensions.

May be repeated.

-f, --of, --format, --output-format <OUTPUT-FORMAT>

Which output raster format to use.

Return status code

The program returns status code 0 in case of success, and non-zero in case of error (non-blocking errors emitted as warnings are considered as a successful execution).

Examples

Example 1: Pipeline running a QGIS processing algorithm to smooth a DEM before computing the hillshade.

```
$ gdal pipeline --config GDAL_ENABLE_EXTERNAL=YES \
    read dem.tif ! \
    external "qgis_process run native:rasterfeaturepreservingsmoothing -- INPUT=<INPUT>␣
↪OUTPUT=<OUTPUT>" ! \
    hillshade ! \
    write out.tif
```

5.1.3 Raster commands

5.1.3.1 gdal raster

Added in version 3.11.

Synopsis

```
Usage: gdal raster <SUBCOMMAND> [OPTIONS]
where <SUBCOMMAND> is one of:
  - as-features:     Create features from pixels of a raster dataset
  - aspect:          Generate an aspect map
  - blend:           Blend/compose two raster datasets
  - calc:            Perform raster algebra
  - clean-collar:    Clean the collar of a raster dataset, removing noise.
  - clip:            Clip a raster dataset.
  - color-map:       Generate a RGB or RGBA dataset from a single band, using a color map
  - compare:         Compare two raster datasets.
  - contour:         Creates a vector contour from a raster elevation model (DEM).
  - convert:         Convert a raster dataset.
  - create:          Create a new raster dataset.
  - edit:            Edit a raster dataset.
  - fill-nodata:     Fill nodata raster regions by interpolation from edges.
  - footprint:       Compute the footprint of a raster dataset.
  - hillshade:       Generate a shaded relief map
  - index:           Create a vector index of raster datasets.
  - info:            Return information on a raster dataset.
  - mosaic:          Build a mosaic, either virtual (VRT) or materialized.
  - neighbors:       Compute the value of each pixel from its neighbors (focal␣
↪statistics) (alias: neighbours)
  - nodata-to-alpha: Replace nodata value(s) with an alpha band.
  - overview:        Manage overviews of a raster dataset.
  - pansharpen:      Perform a pansharpen operation.
  - pipeline:        Process a raster dataset applying several steps.
  - pixel-info:      Return information on a pixel of a raster dataset.
  - polygonize:      Create a polygon feature dataset from a raster band.
  - proximity:       Produces a raster proximity map.
  - reclassify:      Reclassify values in a raster dataset
  - reproject:       Reproject a raster dataset.
  - resize:          Resize a raster dataset without changing the georeferenced extents.
  - rgb-to-palette:  Convert a RGB image into a pseudo-color / paletted image.
  - roughness:       Generate a roughness map
  - scale:           Scale the values of the bands of a raster dataset.
  - select:          Select a subset of bands from a raster dataset.
  - set-type:        Modify the data type of bands of a raster dataset.
  - sieve:           Remove small polygons from a raster dataset.
  - slope:           Generate a slope map
  - stack:           Combine together input bands into a multi-band output, either␣
↪virtual (VRT) or materialized.
  - tile:            Generate tiles in separate files from a raster dataset.
  - tpi:             Generate a Topographic Position Index (TPI) map
  - tri:             Generate a Terrain Ruggedness Index (TRI) map
  - unscale:         Convert scaled values of a raster dataset into unscaled values.
  - update:          Update the destination raster with the content of the input one.
```

(continues on next page)

(continued from previous page)

```
  - viewshed:        Compute the viewshed of a raster dataset.
  - zonal-stats:     Calculate raster zonal statistics

Common Options:
  -h, --help              Display help message and exit
  --json-usage            Display usage as JSON document and exit
  --config <KEY>=<VALUE>  Configuration option [may be repeated]

Options:
  --drivers               Display raster driver list as JSON document
```

Available sub-commands

- *gdal raster info*
- *gdal raster aspect*
- *gdal raster blend*
- *gdal raster calc*
- *gdal raster clean-collar*
- *gdal raster clip*
- *gdal raster color-map*
- *gdal raster compare*
- *gdal raster convert*
- *gdal raster create*
- *gdal raster footprint*
- *gdal raster fill-nodata*
- *gdal raster hillshade*
- *gdal raster index*
- *gdal raster mosaic*
- *gdal raster neighbors*
- *gdal raster nodata-to-alpha*
- *gdal raster overview*
- *gdal raster pipeline*
- *gdal raster pixel-info*
- *gdal raster polygonize*
- *gdal raster proximity*
- *gdal raster reproject*
- *gdal raster resize*
- *gdal raster rgb-to-palette*
- *gdal raster roughness*

- *gdal raster scale*
- *gdal raster select*
- *gdal raster sieve*
- *gdal raster slope*
- *gdal raster stack*
- *gdal raster tile*
- *gdal raster tpi*
- *gdal raster tri*
- *gdal raster unscale*
- *gdal raster update*
- *gdal raster viewshed*

Examples

Example 1: Getting information on the file utm.tif (with text output)

```
$ gdal raster info utm.tif
```

Example 2: Converting file utm.tif to GeoPackage raster

```
$ gdal raster convert utm.tif utm.gpkg
```

Example 3: Getting the list of raster drivers (with JSON output)

```
$ gdal raster --drivers
```

5.1.3.2 gdal raster info

Added in version 3.11.

Synopsis

```
Usage: gdal raster info [OPTIONS] <INPUT>

Return information on a raster dataset.

Positional arguments:
  -i, --dataset, --input <INPUT>                      Input raster dataset [required]␣
↪[not available in pipelines]

Common Options:
  -h, --help                                          Display help message and exit
  --json-usage                                        Display usage as JSON document␣
↪and exit
  --config <KEY>=<VALUE>                              Configuration option [may be␣
↪repeated]
```

(continues on next page)

(continued from previous page)

```
Options:
  -f, --of, --format, --output-format <OUTPUT-FORMAT>  Output format. OUTPUT-
↪FORMAT=json|text
  --mm, --min-max                                      Compute minimum and maximum value
  --stats                                              Retrieve or compute statistics,␣
↪using all pixels
                                                       Mutually exclusive with --approx-
↪stats
  --approx-stats                                       Retrieve or compute statistics,␣
↪using a subset of pixels
                                                       Mutually exclusive with --stats
  --hist                                               Retrieve or compute histogram

Advanced Options:
  --if, --input-format <INPUT-FORMAT>                  Input formats [may be repeated]␣
↪[not available in pipelines]
  --oo, --open-option <KEY>=<VALUE>                    Open options [may be repeated]␣
↪[not available in pipelines]
  --no-gcp                                             Suppress ground control points␣
↪list printing
  --no-md                                              Suppress metadata printing
  --no-ct                                              Suppress color table printing
  --no-fl                                              Suppress file list printing
  --checksum                                           Compute pixel checksum
  --list-metadata-domains, --list-mdd                  List all metadata domains␣
↪available for the dataset
  --mdd, --metadata-domain <METADATA-DOMAIN>           Report metadata for the specified␣
↪domain. 'all' can be used to report metadata in all domains

Esoteric Options:
  --no-nodata                                          Suppress retrieving nodata value
  --no-mask                                            Suppress mask band information
  --subdataset <SUBDATASET>                            Use subdataset of specified index␣
↪(starting at 1), instead of the source dataset itself
  --crs-format <CRS-FORMAT>                            Which format to use to report CRS.
↪ CRS-FORMAT=AUTO|WKT2|PROJJSON (default: AUTO)
```

Description

gdal raster info lists various information about a GDAL supported raster dataset, and returns them on the standard output stream when used from the command line, or in the `output` parameter when used from the API.

The following items will be reported (when known):

- The format driver used to access the file.
- Raster size (in pixels and lines).
- The coordinate system for the file (in short form AUTH_NAME:CODE when possible, or otherwise OGC WKT2:2019).
- The geotransform associated with the file (rotational coefficients are currently not reported).
- Corner coordinates in georeferenced, and if possible lat/long based on the full geotransform (but not GCPs).

- Ground control points.
- File wide (including subdatasets) metadata.
- Band data types.
- Band color interpretations.
- Band block size.
- Band descriptions.
- Band min/max values (internally known and possibly computed).
- Band checksum (if computation asked).
- Band NODATA value.
- Band overview resolutions available.
- Band unit type (i.e.. "meters" or "feet" for elevation bands).
- Band pseudo-color tables.

Starting with GDAL 3.12, **gdal raster info** can be used as the last step of a pipeline.

The following options are available:

Program-Specific Options

--approx-stats

Read and display image statistics. Force computation if no statistics are stored in an image. However, they may be computed based on overviews or a subset of all tiles. Useful if you are in a hurry and don't need precise stats.

--checksum

Force computation of the checksum for each band in the dataset.

-f, --of, --format, --output-format `json|text`

Which output format to use. Default is JSON, and starting with GDAL 3.12, text when invoked from command line.

--crs-format `AUTO|WKT2|PROJJSON`

Added in version 3.13.

Which format to use to report the CRS. In AUTO default mode, if the CRS can be captured with an authority name and code (known of PROJ), only a summary of the CRS, including its name, ID, type and area of use will be reported. Otherwise a full WKT2:2019 definition will be reported.

> **Note**
>
> *--crs-format* can only be set when *--output-format* is set to `text`. The JSON text format includes both WKT2 and PROJJSON.

--hist

Report histogram information for all bands.

--list-mdd

List all metadata domains available for the dataset.

--mdd, --metadata-domain <domain>|all

adds metadata using:

domain Report metadata for the specified domain.

all Report metadata for all domains.

--mm, --min-max

Force computation of the actual min/max values for each band in the dataset.

--no-ct

Suppress printing of color table.

--no-fl

Only display the first file of the file list.

--no-gcp

Suppress ground control points list printing. It may be useful for datasets with huge amount of GCPs, such as L1B AVHRR or HDF4 MODIS which contain thousands of them.

--no-mask

Suppress band mask printing. Is implied if *--no-nodata* is specified.

--no-md

Suppress metadata printing. Some datasets may contain a lot of metadata strings.

--no-nodata

Suppress nodata printing. Implies *--no-mask*.

Can be useful for example when querying a remove GRIB2 dataset that has an index .idx side-car file, together with *--no-md*

--stats

Read and display image statistics. Force computation if no statistics are stored in an image.

--subdataset <n>

If the input dataset contains several subdatasets read and display a subdataset with specified n number (starting from 1). This is an alternative of giving the full subdataset name.

Standard Options

--if, --input-format <format>

Format/driver name to be attempted to open the input file(s). It is generally not necessary to specify it, but it can be used to skip automatic driver detection, when it fails to select the appropriate driver. This option can be repeated several times to specify several candidate drivers. Note that it does not force those drivers to open the dataset. In particular, some drivers have requirements on file extensions.

May be repeated.

--oo, --open-option <NAME>=<VALUE>

Dataset open option (format specific).

May be repeated.

Return status code

The program returns status code 0 in case of success, and non-zero in case of error (non-blocking errors emitted as warnings are considered as a successful execution).

Examples

Example 1: Getting information on the file utmsmall.tif as text output

```
$ gdal raster info utmsmall.tif
Driver: GTiff/GeoTIFF
Files: utmsmall.tif
Size is 100, 100
Coordinate Reference System:
  - name: NAD27 / UTM zone 11N
  - ID: EPSG:26711
  - type: Projected
  - projection type: Transverse Mercator
  - units: metre
Data axis to CRS axis mapping: 1,2
Origin = (440720.000000000000000,3751320.000000000000000)
Pixel Size = (60.000000000000000,-60.000000000000000)
Metadata:
  AREA_OR_POINT=Area
Image Structure Metadata:
  INTERLEAVE=BAND
Corner Coordinates:
Upper Left  (  440720.000, 3751320.000) (117d38'28.21"W, 33d54' 8.47"N)
Lower Left  (  440720.000, 3745320.000) (117d38'26.75"W, 33d50'53.66"N)
Upper Right (  446720.000, 3751320.000) (117d34'34.59"W, 33d54' 9.62"N)
Lower Right (  446720.000, 3745320.000) (117d34'33.28"W, 33d50'54.82"N)
Center      (  443720.000, 3748320.000) (117d36'30.71"W, 33d52'31.66"N)
Band 1 Block=100x81 Type=Byte, ColorInterp=Gray
```

Example 2: Getting information on the file utmsmall.tif as JSON output, including statistics

```
$ gdal raster info --format=JSON --stats utmsmall.tif

Example 3: Check if a remote GeoTIFF is a COG

Search for `LAYOUT=COG` in the `Image Structure Metadata`. The example below uses jq and returns *true* if the remote image is a COG.

Bash

PowerShell

```
$ gdal raster info https://sentinel-cogs.s3.us-west-2.amazonaws.com/sentinel-s2-l2a-cogs/
↪36/Q/WD/2020/7/S2A_36QWD_20200701_0_L2A/TCI.tif --of=JSON \
| jq '.metadata.IMAGE_STRUCTURE.LAYOUT == "COG"'
```

```
> gdal raster info https://sentinel-cogs.s3.us-west-2.amazonaws.com/sentinel-s2-l2a-cogs/
↪36/Q/WD/2020/7/S2A_36QWD_20200701_0_L2A/TCI.tif --of=JSON `
| jq '.metadata.IMAGE_STRUCTURE.LAYOUT == \"COG\"'
```

Example 4: Return the CRS used by the raster using jq

Bash

PowerShell

```
gdal raster info in.tif --of json | jq -r '.stac."proj:projjson".id | .authority + ":" +␣
↪(.code|tostring)'
```

```
gdal raster info in.tif --of json | jq -r '.stac.\"proj:projjson\".id | .authority + \":\
↪" + (.code|tostring)'
```

5.1.3.3 gdal raster as-features

Added in version 3.12.

Synopsis

```
Usage: gdal raster as-features [OPTIONS] <INPUT> <OUTPUT>

Create features from pixels of a raster dataset

↪repeated] [not available in pipelines]
```

Description

gdal raster as-features creates features representing the pixels in a raster dataset. Features may be created as polygons, points, or with no geometry at all. Unlike *gdal raster polygonize*, adjacent pixels having the same values are not combined.

This algorithm can be part of a *gdal pipeline*.

Program-Specific Options

-b, --band <band>

Specifies the bands for which pixel values should be added as fields of the created features. By default, values will be added for all bands.

--geometry-type

Specifies the geometry type of the created features. Options available are "none" (default), "point", or "polygon".

--include-row-col

If set, ROW and COL fields will be added with the cell positions.

--include-xy

If set, CENTER_X and CENTER_Y fields will be added with the center coordinates of each pixel.

--output-layer

Provides a name for the output vector layer. Defaults to "pixels".

--skip-nodata

If set, no features will be emitted for pixels equal to the NoData value.

Standard Options

--append

Whether appending features to existing layer(s) is allowed. This also creates the output dataset if it does not exist yet.

--co, --creation-option <NAME>=<VALUE>

Many formats have one or more optional creation options that can be used to control particulars about the file created. For instance, the GeoTIFF driver supports creation options to control compression, and whether the file should be tiled.

May be repeated.

The creation options available vary by format driver, and some simple formats have no creation options at all. A list of options supported for a format can be listed with the *--formats* command line option but the documentation for the format is the definitive source of information on driver creation options. See *Raster drivers* format specific documentation for legal creation options for each format.

--if, --input-format <format>

Format/driver name to be attempted to open the input file(s). It is generally not necessary to specify it, but it can be used to skip automatic driver detection, when it fails to select the appropriate driver. This option can be repeated several times to specify several candidate drivers. Note that it does not force those drivers to open the dataset. In particular, some drivers have requirements on file extensions.

May be repeated.

--lco, --layer-creation-option <NAME>=<VALUE>

Many formats have one or more optional layer creation options that can be used to control particulars about the layer created. For instance, the GeoPackage driver supports layer creation options to control the feature identifier or geometry column name, setting the identifier or description, etc.

May be repeated.

The layer creation options available vary by format driver, and some simple formats have no layer creation options at all. A list of options supported for a format can be listed with the *--formats* command line option but the documentation for the format is the definitive source of information on driver creation options. See *Vector drivers* format specific documentation for legal creation options for each format.

Note that layer creation options are different from dataset creation options.

--oo, --open-option <NAME>=<VALUE>

Dataset open option (format specific).

May be repeated.

-f, --of, --format, --output-format <OUTPUT-FORMAT>

Which output vector format to use. Allowed values may be given by `gdal --formats | grep vector | grep rw | sort`

--output-open-option, --output-oo <NAME>=<VALUE>

Added in version 3.12.

Dataset open option for output dataset (format specific).

May be repeated.

--overwrite

Allow program to overwrite existing target file or dataset. Otherwise, by default, **gdal** errors out if the target file or dataset already exists.

--overwrite-layer

Whether overwriting the existing output vector layer is allowed.

--update

Whether to open an existing output dataset in update mode.

Return status code

The program returns status code 0 in case of success, and non-zero in case of error (non-blocking errors emitted as warnings are considered as a successful execution).

Examples

Example 1: Create points at the center of pixels having a value less than 150

```
gdal pipeline read input.tif !
         reclassify -m "[-inf, 150)=1; DEFAULT=NO_DATA" !
         as-features --geometry-type point --skip-nodata !
         write out.shp
```

Example 2: Create a polygon grid dividing the globe into 1-degree chunks

```
gdal pipeline create --bbox -180,-90,180,90 --size 360,180 !
         as-features --geometry-type polygon !
         write grid.shp
```

5.1.3.4 gdal raster aspect

Added in version 3.11.

Synopsis

```
Usage: gdal raster aspect [OPTIONS] <INPUT> <OUTPUT>

Generate an aspect map

Positional arguments:
  -i, --input <INPUT>                                    Input raster datasets [required]␣
↪[not available in pipelines]
  -o, --output <OUTPUT>                                  Output raster dataset [required]␣
↪[not available in pipelines]

Common Options:
  -h, --help                                             Display help message and exit
  --json-usage                                           Display usage as JSON document␣
↪and exit
  --config <KEY>=<VALUE>                                 Configuration option [may be␣
↪repeated]
  -q, --quiet                                            Quiet mode (no progress bar or␣
↪warning message) [not available in pipelines]

Options:
  -f, --of, --format, --output-format <OUTPUT-FORMAT>  Output format ("GDALG" allowed)␣
↪[not available in pipelines]

↪CONVENTION=azimuth|trigonometric-angle (default: azimuth)
  --gradient-alg <GRADIENT-ALG>                          Algorithm used to compute terrain␣
↪gradient. GRADIENT-ALG=Horn|ZevenbergenThorne (default: Horn)
  --zero-for-flat                                        Whether to output zero for flat␣
↪areas
  --no-edges                                             Do not try to interpolate values␣
↪at dataset edges or close to nodata values

Advanced Options:
  --if, --input-format <INPUT-FORMAT>                    Input formats [may be repeated]␣
↪[not available in pipelines]
  --oo, --open-option <KEY>=<VALUE>                      Open options [may be repeated]␣
↪[not available in pipelines]
```

Description

gdal raster aspect generates an aspect map, from any GDAL-supported elevation raster.

This subcommand is also available as a potential step of *gdal raster pipeline*

It outputs a 32-bit float raster with values between 0° and 360° representing the azimuth that slopes are facing. The definition of the azimuth is such that: - 0° means that the slope is facing the North, - 90° it's facing the East, - 180° it's facing the South - and 270° it's facing the West (provided that the top of your input raster is north oriented).

The aspect value -9999 is used as the nodata value to indicate undefined aspect in flat areas with slope=0.

A nodata value in the target dataset will also be emitted if at least one pixel set to the nodata value is found in the 3x3 window centered around each source pixel. By default, the algorithm will compute values at image edges or if a nodata value is found in the 3x3 window, by interpolating missing values, unless `--no-edges` is specified, in which case a 1-pixel border around the image will be set with the nodata value.

GDALG output (on-the-fly / streamed dataset)

This program supports serializing the command line as a JSON file using the `GDALG` output format. The resulting file can then be opened as a raster dataset using the *GDALG: GDAL Streamed Algorithm* driver, and apply the specified pipeline in a on-the-fly / streamed way.

Program-Specific Options

-b, --band <BAND>

Index (starting at 1) of the band to which the aspect must be computed.

--convention `azimuth|trigonometric-angle`

Convention for output angles.

Defaults to `azimuth`, that is to say: - 0° means that the slope is facing the North, - 90° it's facing the East, - 180° it's facing the South - and 270° it's facing the West (provided that the top of your input raster is north oriented).

If set to `trigonometric-angle`, - 0° means that the slope is facing the East, - 90° it's facing the North, - 180° it's facing the West - and 270° it's facing the South

--gradient-alg `Horn|ZevenbergenThorne`

Algorithm used to compute terrain gradient. The default is `Horn`. The literature suggests Zevenbergen & Thorne to be more suited to smooth landscapes, whereas Horn's formula to perform better on rougher terrain.

--no-edges

Do not try to interpolate values at dataset edges or close to nodata values

--zero-for-flat

Whether to output zero for flat areas. By default, flat areas where the slope is null will be assigned a nodata value (-9999). When setting this option, they are set to 0.

Standard Options

--append

Append input raster as a new subdataset to an existing output file. Only works with drivers that support adding subdatasets such as *GTiff -- GeoTIFF File Format* and *GPKG -- GeoPackage raster* This also creates the output dataset if it does not exist yet.

--co, --creation-option <NAME>=<VALUE>

Many formats have one or more optional creation options that can be used to control particulars about the file created. For instance, the GeoTIFF driver supports creation options to control compression, and whether the file should be tiled.

May be repeated.

The creation options available vary by format driver, and some simple formats have no creation options at all. A list of options supported for a format can be listed with the *--formats* command line option but the documentation for the format is the definitive source of information on driver creation options. See *Raster drivers* format specific documentation for legal creation options for each format.

--if, --input-format <format>

Format/driver name to be attempted to open the input file(s). It is generally not necessary to specify it, but it can be used to skip automatic driver detection, when it fails to select the appropriate driver. This option can be repeated several times to specify several candidate drivers. Note that it does not force those drivers to open the dataset. In particular, some drivers have requirements on file extensions.

May be repeated.

--oo, --open-option <NAME>=<VALUE>

Dataset open option (format specific).

May be repeated.

-f, --of, --format, --output-format <OUTPUT-FORMAT>

Which output raster format to use. Allowed values may be given by `gdal --formats | grep raster | grep rw | sort`

--overwrite

Allow program to overwrite existing target file or dataset. Otherwise, by default, **gdal** errors out if the target file or dataset already exists.

Return status code

The program returns status code 0 in case of success, and non-zero in case of error (non-blocking errors emitted as warnings are considered as a successful execution).

Examples

Example 1: Generates an aspect map from a DTED0 file.

```
$ gdal raster aspect n43.dt0 out.tif --overwrite
```

5.1.3.5 gdal raster blend

Added in version 3.12.

Synopsis

```
Usage: gdal raster blend [OPTIONS] <COLOR-INPUT> <OVERLAY> <OUTPUT>

Blend/compose two raster datasets

```

Description

gdal raster blend allows the user to compose two raster datasets (of the same size) using a selected blending operation and an opacity setting.

This can be used for example to colorize a hillshade raster generated by *gdal raster hillshade* with an hypsometric rendering of a DEM generated by *gdal raster color-map* when using the `hsv-value` blending operator.

The more standard `src-over` blending operator, which does "alpha blending" is also available.

This subcommand is also available as a potential step of *gdal raster pipeline*

GDALG output (on-the-fly / streamed dataset)

This program supports serializing the command line as a JSON file using the `GDALG` output format. The resulting file can then be opened as a raster dataset using the *GDALG: GDAL Streamed Algorithm* driver, and apply the specified pipeline in a on-the-fly / streamed way.

Program-Specific Options

--input <INPUT>

Name of the dataset into which to blend the overlay dataset. Required.

When using the `hsv-value` blending operator, this must be a three-band or four-band Byte raster.

--opacity <OPACITY>

Opacity to use when blending the overlay dataset, as a percentage between 0 and 100. 0 means that the overlay dataset is considered fully transparent. 100 means that the overlay dataset is blended at the maximum of its alpha channel. Defaults to 100.

--operator `src-over|hsv-value|multiply|screen|overlay|hard-light|lighten|darken`

Select the blending operator, which defines how the overlay dataset is blended into the input dataset. Defaults to `src-over`.

See *Details of blending operations* below for details about each operator.

--overlay <OVERLAY>

Name of the overlay dataset. Required

Standard Options

--append

Append input raster as a new subdataset to an existing output file. Only works with drivers that support adding subdatasets such as *GTiff -- GeoTIFF File Format* and *GPKG -- GeoPackage raster* This also creates the output dataset if it does not exist yet.

--co, --creation-option <NAME>=<VALUE>

Many formats have one or more optional creation options that can be used to control particulars about the file created. For instance, the GeoTIFF driver supports creation options to control compression, and whether the file should be tiled.

May be repeated.

The creation options available vary by format driver, and some simple formats have no creation options at all. A list of options supported for a format can be listed with the *--formats* command line option but the documentation for the format is the definitive source of information on driver creation options. See *Raster drivers* format specific documentation for legal creation options for each format.

--if, --input-format <format>

Format/driver name to be attempted to open the input file(s). It is generally not necessary to specify it, but it can be used to skip automatic driver detection, when it fails to select the appropriate driver. This option can be repeated several times to specify several candidate drivers. Note that it does not force those drivers to open the dataset. In particular, some drivers have requirements on file extensions.

May be repeated.

--oo, --open-option <NAME>=<VALUE>

Dataset open option (format specific).

May be repeated.

-f, --of, --format, --output-format <OUTPUT-FORMAT>

Which output raster format to use. Allowed values may be given by `gdal --formats | grep raster | grep rw | sort`

--overwrite

Allow program to overwrite existing target file or dataset. Otherwise, by default, **gdal** errors out if the target file or dataset already exists.

Details of blending operations

In the description of the blending operations, all values are normalized to [0,1] range and each channel value is premultiplied with the alpha channel value.

The following notations are used:

- $overlay_C$ is the value of one of the red, green or blue component of the overlay dataset,
- $overlay_A$ is the value of the alpha component of the overlay dataset premultiplied by `--opacity`,
- $input_C$ is the value of the corresponding component of the input dataset,
- $input_A$ is the value of the alpha component of the input dataset
- $output_C$ is the resulting component of the output dataset,
- $opacity$ is the value of `--opacity`

> **Note**
>
> For efficiency, the implementation uses integer arithmetic on [0,255] range rather than floating point arithmetic on [0,1] range. This can explain minor differences with the formulas described below.

For all operator (unless otherwise specified) the alpha channel is computed as:

$$output_A = overlay_A + input_A - overlay_A * input_A$$

The following blending operators are available:

Table 1: Overview of raster blend operators

Operator	Description	Example
`src-over`	Standard alpha blending (overlay composited over input)	`hsv-value`	Uses value from overlay and hue/saturation from input	`multiply`	Multiplies input and overlay colors	`screen`	Complement then multiply colors	`overlay`	Combines multiply and screen	`hard-light`	Multiply or screen depending on overlay brightness	
- **`src-over` performs standard alpha blending, by compositing the overlay**
  dataset over the input dataset.

  The following formula is applied for each of the red, green and blue components:

  $$output_C * output_A = (overlay_C * overlay_A * opacity) + (input_C * input_A * (1 - overlay_A * opacity))$$

- **`hsv-value` creates a color with the value of the overlay and the hue**
  and saturation of the input. It performs the following steps:

  - read the RGB (Red,Green,Blue) components of the input dataset
  - transform the RGB components into the HSV (Hue,Saturation,Value) color space
  - compute the output value $output_V$, using the following formula:

    $$output_V = (overlay_V * overlay_A * opacity) + (input_V * (1 - overlay_A * opacity))$$

  If the overlay dataset is a RGB/RGBA dataset, $overlay_V$ is $max(overlay_R, overlay_G, overlay_B)$.

  - transform back (Hue,Saturation,:math:*output_{V}*) to RGB.

  If the the alpha channel of the input dataset is present, it is preserved unchanged.

- **`multiply` multiplies the input and overlay colors.**
  The resulting color is always at least as dark as either of the two constituent colors.

  The following formula is applied for each of the red, green and blue components:

  $$output_C = overlay_C * input_C + input_C * (1 - overlay_A) + overlay_C * (1 - input_A)$$

- `screen` The overlay and input are complemented and then multiplied. The resultant color is always at least as light as either of the two constituent colors. Screening any color with white produces white. Screening any color with black leaves the original color unchanged.

  The following formula is applied for each of the red, green and blue components:

  $$output_C = overlay_C + input_C - overlay_C * input_C$$

- `overlay` Overlay combines Multiply and Screen blend modes, at half strength. The parts of the overlay layer where the input layer is light become lighter, the parts where the input layer is dark become darker. Areas where the overlay layer are mid grey are unaffected.

  The following formula is applied for each of the red, green and blue components:

  If the input component is less than 0.5 (dark):

  $$output_C = 2 * overlay_C * input_C + input_C * (1 - overlay_A) + overlay_C * (1 - input_A)$$

  If the input component is greater than or equal to 0.5 (light):

  $$output_C = overlay_A * input_A - 2 * (input_A - input_C) * (overlay_A - overlay_C) + input_C * (1 - overlay_A) + overl$$

- `hard-light` The overlay is used to either multiply or screen the input, depending on the overlay color value. If the overlay color value is lighter than 50% gray, the input is screened, otherwise it is multiplied. This is useful for adding highlights or shadows to an image. The implementation is the same of `overlay` but with the roles of input and overlay swapped.

The following formula is applied for each of the red, green and blue components:

If the overlay component is less than 0.5 (dark):

$$output_C = overlay_A * input_A - 2 * (input_A - input_C) * (overlay_A - overlay_C) + input_C * (1 - overlay_A) + overl$$

If the overlay component is greater than or equal to 0.5 (light):

$$output_C = 2 * overlay_C * input_C + input_C * (1 - overlay_A) + overlay_C * (1 - input_A)$$

- `darken` Creates a image that retains the smallest components of the overlay and input pixels. If the overlay pixel has the components r1, g1, and b1, and the input pixel has r2, g2, b2, the resultant pixel is [min(r1,r2), min(g1,g2), min(b1,b2)]

  The following formula is applied for each of the red, green and blue components:

  $$output_C = min(overlay_C, input_C) + input_C * (1 - overlay_A) + overlay_C * (1 - input_A)$$

- `lighten` Lighten has the opposite action of Darken. It selects the maximum of each component from the overlay and input pixels. If the overlay pixel has the components r1, g1, and b1, and the input pixel has r2, g2, b2, the resultant pixel is [max(r1,r2), max(g1,g2), max(b1,b2)]

  The following formula is applied for each of the red, green and blue components:

  $$output_C = max(overlay_C, input_C) + input_C * (1 - overlay_A) + overlay_C * (1 - input_A)$$

- `color-dodge` Divides the input layer by the inverted overlay layer. This lightens the input layer depending on the value of the overlay layer: the brighter the overlay layer, the more its color affects the input layer. Blending any color with white gives white. Blending with black does not change the image.

  The following formula is applied for each of the red, green and blue components:

  If the $overlay_C * input_A$ is greater than or equal to $overlay_A * input_A$ then:

  $$output_C = overlay_A * input_A + input_C * (1 - overlay_A) + overlay_C * (1 - input_A)$$

  If the $overlay_C * input_A$ is less than $overlay_A * input_A$ then:

  $$output_C = input_C * overlay_A/(1 - overlay_C/overlay_A) + overlay_C * (1 - input_A) + input_C * (1 - overlay_A)$$

- `color-burn` Divides the inverted input layer by the overlay layer, and then inverts the result. This darkens the overlay layer increasing the contrast to reflect the color of the input layer. The darker the input layer, the more its color is used.

  The following formula is applied for each of the red, green and blue components:

  If the $overlay_C * input_A$ is greater than or equal to $overlay_A * input_A$ then:

  $$output_C = overlay_A * input_A + input_C * (1 - overlay_A) + overlay_C * (1 - input_A)$$

  If the $overlay_C * input_A$ is greater than $overlay_A * input_A$ then:

  $$output_C = input_C * overlay_A/(1 - overlay_C/overlay_A) + overlay_C * (1 - input_A) + input_C * (1 - overlay_A)$$

Return status code

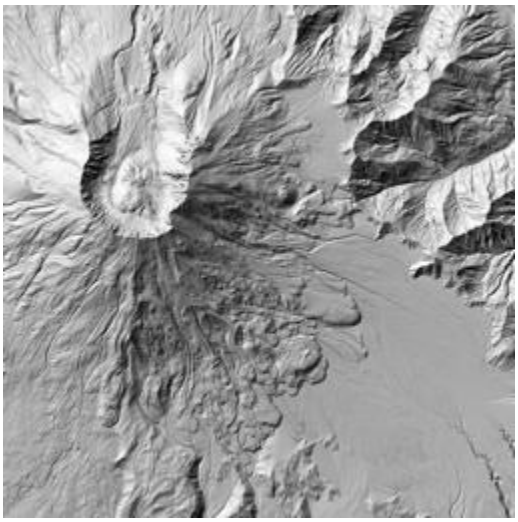
The program returns status code 0 in case of success, and non-zero in case of error (non-blocking errors emitted as warnings are considered as a successful execution).

Examples

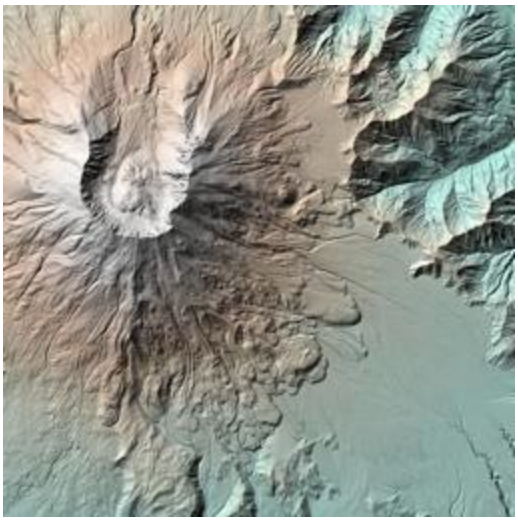
Example 1: Alpha blending of two datasets using 75% opacity for the overlay dataset.

```
$ gdal raster blend --opacity 75 source.tif overlay.tif out.tif
```

Example 2: Combine a hillshade and a hypsometric rendering of a DEM into a colorized hillshade using the hsv-value blending operator.

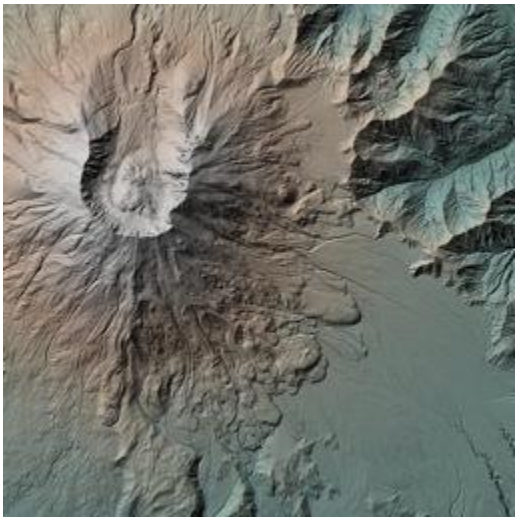


```
$ gdal raster blend --overlay=hillshade.tif --operator=hsv-value \
                    hypsometric.tif hypsometric_combined_with_hillshade.tif
```



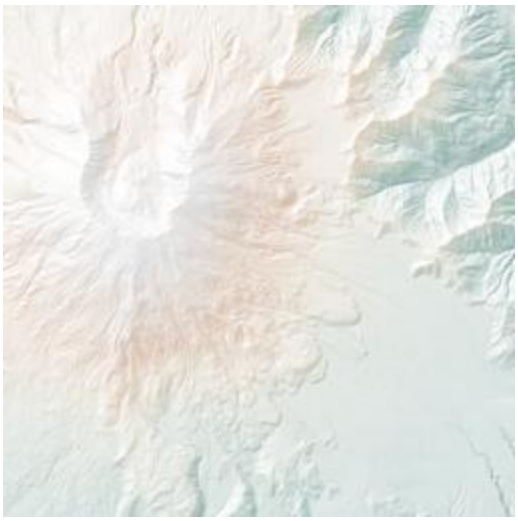
Example 3: Combine a hillshade and a hypsometric rendering of a DEM into a colorized hillshade using the multiply blending operator.

```
$ gdal raster blend --overlay=hillshade.tif --operator=multiply \
                    hypsometric.tif hypsometric_combined_with_hillshade.tif
```



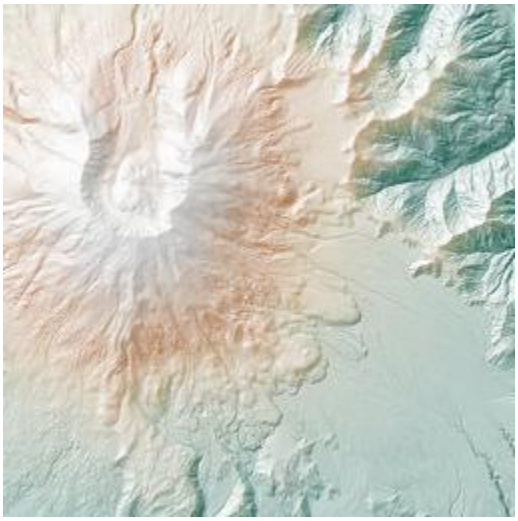
Example 4: Combine a hillshade and a hypsometric rendering of a DEM into a colorized hillshade using the screen blending operator.

```
$ gdal raster blend --overlay=hillshade.tif --operator=screen \
                    hypsometric.tif hypsometric_combined_with_hillshade.tif
```



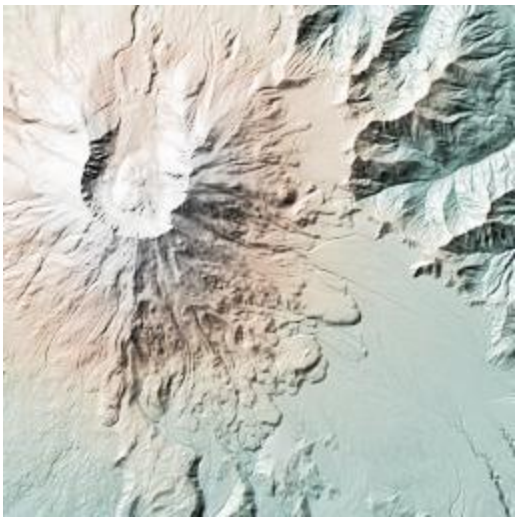
Example 5: Combine a hillshade and a hypsometric rendering of a DEM into a colorized hillshade using the overlay blending operator.

```
$ gdal raster blend --overlay=hillshade.tif --operator=overlay \
                    hypsometric.tif hypsometric_combined_with_hillshade.tif
```



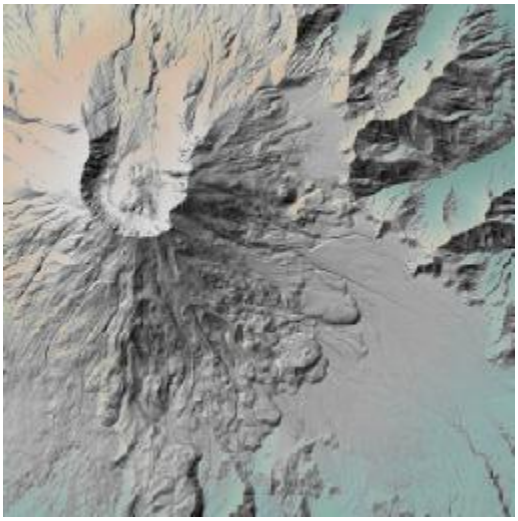
Example 6: Combine a hillshade and a hypsometric rendering of a DEM into a colorized hillshade using the hard-light blending operator.

```
$ gdal raster blend --overlay=hillshade.tif --operator=hard-light \
                    hypsometric.tif hypsometric_combined_with_hillshade.tif
```



Example 7: Combine a hillshade and a hypsometric rendering of a DEM into a colorized hillshade using the darken blending operator.

```
$ gdal raster blend --overlay=hillshade.tif --operator=darken \
                    hypsometric.tif hypsometric_combined_with_hillshade.tif
```



Example 8: Combine a hillshade and a hypsometric rendering of a DEM into a colorized hillshade using the lighten blending operator.

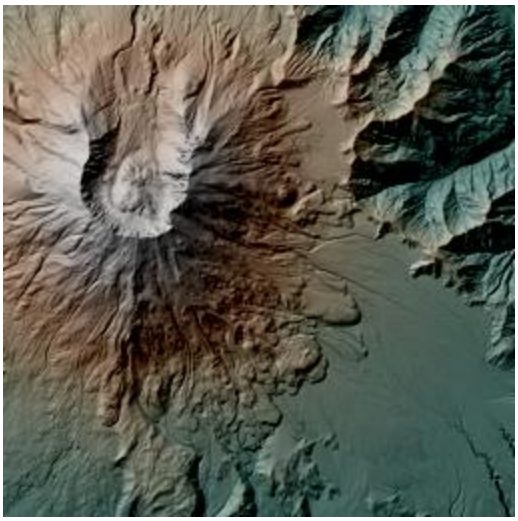
```
$ gdal raster blend --overlay=hillshade.tif --operator=lighten \
                    hypsometric.tif hypsometric_combined_with_hillshade.tif
```

Example 9: Combine a hillshade and a hypsometric rendering of a DEM into a colorized hillshade using the color-dodge blending operator.

```
$ gdal raster blend --overlay=hillshade.tif --operator=color-dodge \
                    hypsometric.tif hypsometric_combined_with_hillshade.tif
```

Example 10: Combine a hillshade and a hypsometric rendering of a DEM into a colorized hillshade using the color-burn blending operator.

```
$ gdal raster blend --overlay=hillshade.tif --operator=color-burn \
                    hypsometric.tif hypsometric_combined_with_hillshade.tif
```



5.1.3.6 gdal raster calc

```

Description

gdal raster calc performs pixel-wise calculations on one or more input GDAL datasets. Calculations can be performed eagerly, writing results to a conventional raster format, or lazily, written as a set of derived bands in a *VRT (Virtual Dataset)*.

The list of input GDAL datasets can be specified at the end of the command line or put in a text file (one input per line) for very long lists. If more than one input dataset is used, it should be prefixed with a name by which it will be referenced in the calculation, e.g. `A=my_data.tif`. (If a single dataset is used, it will be referred to with the variable `X` in formulas.)

Starting with GDAL 3.12, it is also possible to use a *VRT C++ pixel function* (such a `sum`, `mean`, `min`, `max`) by specifying `--dialect` to `builtin`.

The inputs should have the same spatial reference system and should cover the same spatial extent but are not required to have the same spatial resolution. The spatial extent check can be disabled with `--no-check-extent`, in which case the inputs must have the same dimensions. The spatial reference system check can be disabled with `--no-check-crs`.

Since GDAL 3.12, this algorithm can be part of a *gdal pipeline* or *gdal raster pipeline*.

GDALG output (on-the-fly / streamed dataset)

This program supports serializing the command line as a JSON file using the `GDALG` output format. The resulting file can then be opened as a raster dataset using the *GDALG: GDAL Streamed Algorithm* driver, and apply the specified pipeline in a on-the-fly / streamed way.

Program-Specific Options

--calc

An expression to be evaluated using the muparser math parser library. The expression may refer to individual bands of each input (e.g., `X[1] + 3`) or it may be applied to all bands of an input (`X + 3`).

There are two methods by which an expression may be applied to multiple bands. In the default method, the expression is applied to each band individually, resulting in one output band for each input band. For example, with a three-band input `X`, the expression `--calc "X+3"` would be expanded into `--calc "X[1]+3" --calc "X[2]+3" --calc "X[3]+3"`. If the expression contains a reference to all bands of multiple inputs, those inputs must either have the same number of bands, or a single band. For example, if inputs `A` and `B` each have three bands, and input `C` has a single band, then the argument `--calc "A + B + C"` is equivalent to `--calc "A[1] + B[1] + C[1]" --calc "A[2] + B[2] + C[1]" --calc "A[3] + B[3] + C[1]"`. Similarly, `--calc "sum(A,B,C)"` would be expanded to `--calc "sum(A[1], B[1], C[1]" --calc "sum(A[2], B[2], C[1])" --calc "sum(A[3], B[3], C[1])"`.

In the second method, which is enabled with *`--flatten`*, aggregate functions (`sum`, `avg`, `min`, and `max`) invoked on multiple bands will be applied to all bands in aggregate. In this case, `sum(A)` is expanded into `sum(A[1], A[2], A[3])`, and `sum(A,C)` is expanded into `sum(A[1], A[2], A[3], C[1])`. If the expression consists _only_ of aggregate functions, this will produce a single output band no matter how many input bands are present. However, if the expression contains a non-aggregate reference to all bands of an input, then one output band will still be produced for each input band. A simple example is the expression `A / sum(A)`, which would produce an N-band raster where each output band contains the input band's fraction of the total.

Multiple calculations may be specified; output band(s) will be produced for each expression in the order they are provided.

Input rasters will be converted to 64-bit floating point numbers before performing calculations.

Starting with GDAL 3.12, it is also possible to use a *VRT C++ pixel function* (such a `sum`, `mean`, `min`, `max`) by specifying *`--dialect`* to `builtin`. Arguments to functions are passed within parentheses, like `sum(k=1)`, `min(propagateNoData=true)` or `interpolate_linear(t0=1,dt=1,t=10)`.

Built-in variables

The following built-in variables are available in expressions:

- `_CENTER_X_`: X coordinate of the pixel center, expressed in the dataset CRS
- `_CENTER_Y_`: Y coordinate of the pixel center, expressed in the dataset CRS
- `NODATA`: The output *NoData* value, if any.

These variables are useful for calculations that depend on spatial position, such as latitude-based corrections, solar angle approximations, or zonal masks.

See *Example 7* for a usage example.

Note: To work with longitude/latitude values, the input dataset must be in a geographic coordinate reference system (for example, EPSG:4326).

--dialect `muparser|builtin`

Added in version 3.12.

Specify the expression engine used to interpret the value of *`--calc`*. The default is `muparser`.

--flatten

Added in version 3.12.

Generate a single band output raster per expression, even if input datasets are multiband.

For the default muparser dialect, using the name of an input raster (let's say A) is equivalent to `A[1],A[2],...,A[n]`. Such syntax works with the `min`, `max`, `sum` and `avg` muparser functions.

For example, let's consider 2 rasters A and B with 3bands each, then `--flatten --calc "avg(A)-avg(B)"` is equivalent to `--calc "avg(A[1],A[2],A[3])-avg(B[1],B[2],B[3])"`

And `--flatten --dialect=builtin --calc mean` will compute a single band with the average of all 4 input bands.

-i [<name>=]<input>

Select an input dataset to be processed. If more than one input dataset is provided, each dataset must be prefixed with a name to which it will will be referenced in *--calc*.

--no-check-extent

Do not verify that the input rasters have the same spatial extent. The input rasters will instead be required to have the same dimensions. The geotransform of the first input will be assigned to the output.

--no-check-crs

Do not check the spatial reference systems of the inputs for consistency. All inputs will be assumed to have the spatial reference system of the first input, and this spatial reference system will be used for the output.

--nodata

Added in version 3.12.

Set the NoData value for the output dataset. May be set to "none" to leave the NoData value undefined. If *--nodata* is not specified, **gdal raster calc** will use a NoData value from the first source dataset to have one.

--propagate-nodata

Added in version 3.12.

If set, a NoData value in any input dataset used an in expression will cause the output value to be NoData.

Standard Options

--append

Append input raster as a new subdataset to an existing output file. Only works with drivers that support adding subdatasets such as *GTiff -- GeoTIFF File Format* and *GPKG -- GeoPackage raster* This also creates the output dataset if it does not exist yet.

--co, --creation-option <NAME>=<VALUE>

Many formats have one or more optional creation options that can be used to control particulars about the file created. For instance, the GeoTIFF driver supports creation options to control compression, and whether the file should be tiled.

May be repeated.

The creation options available vary by format driver, and some simple formats have no creation options at all. A list of options supported for a format can be listed with the *--formats* command line option but the documentation for the format is the definitive source of information on driver creation options. See *Raster drivers* format specific documentation for legal creation options for each format.

--if, --input-format <format>

Format/driver name to be attempted to open the input file(s). It is generally not necessary to specify it, but it can be used to skip automatic driver detection, when it fails to select the appropriate driver. This option can be repeated several times to specify several candidate drivers. Note that it does not force those drivers to open the dataset. In particular, some drivers have requirements on file extensions.

May be repeated.

--oo, --open-option <NAME>=<VALUE>

Dataset open option (format specific).

May be repeated.

-f, --of, --format, --output-format <OUTPUT-FORMAT>

Which output raster format to use. Allowed values may be given by `gdal --formats | grep raster | grep rw | sort`

--ot, --datatype, --output-data-type <OUTPUT-DATA-TYPE>

Output data type among `Byte`, `Int8`, `UInt16`, `Int16`, `UInt32`, `Int32`, `UInt64`, `Int64`, `CInt16`, `CInt32`, `Float32`, `Float64`, `CFloat32`, `CFloat64`.

--overwrite

Allow program to overwrite existing target file or dataset. Otherwise, by default, **gdal** errors out if the target file or dataset already exists.

Return status code

The program returns status code 0 in case of success, and non-zero in case of error (non-blocking errors emitted as warnings are considered as a successful execution).

Examples

Example 1: Per-band sum of three files

```
gdal raster calc -i "A=file1.tif" -i "B=file2.tif" -i "C=file3.tif" --calc "A+B+C" -o␣
↪out.tif
```

Example 2: Per-dataset average of all bands of each dataset

```
gdal raster calc -i "A=file1.tif" -i "B=file2.tif" -i "C=file3.tif" --flatten --calc
↪"avg(A)" --calc "avg(B)" --calc "avg(C)" -o out.tif
```

Example 3: Per-band maximum of three files

```
gdal raster calc -i "A=file1.tif" -i "B=file2.tif" -i "C=file3.tif" --calc "max(A,B,C)" -
↪o out.tif
```

Example 4: Setting values of zero and below to NaN

```
gdal raster calc -i "A=input.tif" -o result.tif --calc="A > 0 ? A : NaN"
```

Example 5: Compute the average (as a single band) of all bands of two input datasets

```
gdal raster calc -i A=input1.tif -i B=input2.tif -o result.tif --flatten --calc=mean --
↪dialect=builtin
```

Example 6: Generate a masked aspect layer where the slope angle is greater than 2 degrees, using nested pipelines (since GDAL 3.12.1)

```
gdal raster calc -i "SLOPE=[ read dem.tif ! slope ]" -i "ASPECT=[ read dem.tif ! aspect ]
↪" -o result.tif --calc "(SLOPE >= 2) ? ASPECT : -9999" --nodata -9999
```

Example 7: Latitude-based calculation using _CENTER_Y_

```
gdal raster calc -i A=input.tif \
    --calc="sin(_CENTER_Y_ * 0.0174533)" \
    -o output.tif
```

5.1.3.7 gdal raster clean-collar

Added in version 3.11.

Synopsis

```
Usage: gdal raster clean-collar [OPTIONS] <INPUT> [<OUTPUT>]

Clean the collar of a raster dataset, removing noise.

Positional arguments:
  -i, --input <INPUT>                                    Input raster dataset [required]
  -o, --output <OUTPUT>                                  Output raster dataset

Common Options:
  -h, --help                                             Display help message and exit
  --json-usage                                           Display usage as JSON document␣
↪and exit
  --config <KEY>=<VALUE>                                 Configuration option [may be␣
↪repeated]

  --if, --input-format <INPUT-FORMAT>                   Input formats [may be repeated]
```

Description

gdal raster clean-collar scans a (8-bit) image and sets all pixels that are nearly or exactly black (the default), white or one or more custom colors around the collar to black or white. This is often used to "fix up" lossy compressed air photos so that color pixels can be treated as transparent when mosaicing. The output format must use lossless compression if either alpha band or mask band is not set.

Program-Specific Options

--add-alpha

Adds an alpha band to the output file. The alpha band is set to 0 in the image collar and to 255 elsewhere. This option is mutually exclusive with *--add-mask*.

--add-mask

Adds a mask band to the output file, The mask band is set to 0 in the image collar and to 255 elsewhere. This option is mutually exclusive with *--add-alpha*.

--algorithm `floodfill|twopasses`

Selects the algorithm to apply.

`twopasses` uses a top-to-bottom pass followed by a bottom-to-top pass. It may miss with concave areas. The algorithm processes the image one scanline at a time. A scan "in" is done from either end setting pixels to black or white until at least "non_black_pixels" pixels that are more than "dist" gray levels away from black, white or custom colors have been encountered at which point the scan stops. The nearly black, white or custom color pixels are set to black or white. The algorithm also scans from top to bottom and from bottom to top to identify indentations in the top or bottom.

`floodfill` (default) uses the Flood Fill algorithm and will work with concave areas. It requires creating a temporary dataset and is slower than `twopasses`. When a non-zero value for *--pixel-distance* is used, `twopasses` is actually called as an initial step of `floodfill`.

--color `<c1>,<c2>,<c3>...<cn>|black|white`

Search for pixels near the specified color. May be specified multiple times. When this option is specified, the pixels that are considered as the collar are set to 0, unless only white is specified, in which case there are set to 255.

--color-threshold `<val>`

Select how far from black, white or custom colors the pixel values can be and still considered near black, white or custom color. Defaults to 15.

--pixel-distance `<val>`

Number of consecutive transparent pixels that can be encountered before the giving up search inwards. Said otherwise, the collar will be extended by this number of pixels. Defaults to 2.

Standard Options

--co, --creation-option <NAME>=<VALUE>

Many formats have one or more optional creation options that can be used to control particulars about the file created. For instance, the GeoTIFF driver supports creation options to control compression, and whether the file should be tiled.

May be repeated.

The creation options available vary by format driver, and some simple formats have no creation options at all. A list of options supported for a format can be listed with the *--formats* command line option but the documentation for the format is the definitive source of information on driver creation options. See *Raster drivers* format specific documentation for legal creation options for each format.

-f, --of, --format, --output-format <OUTPUT-FORMAT>

Which output raster format to use. Allowed values may be given by `gdal --formats | grep raster | grep + | sort`

--overwrite

Allow program to overwrite existing target file or dataset. Otherwise, by default, **gdal** errors out if the target file or dataset already exists.

--update

If only an input dataset is specified, ask for it to be opened in update mode If an output dataset is specified, ask for it to be opened in update mode (this implies that it already exists). Note that updating an existing dataset may lead to file size increase if the dataset is compressed, and/or quality loss if lossy compression is used.

Return status code

The program returns status code 0 in case of success, and non-zero in case of error (non-blocking errors emitted as warnings are considered as a successful execution).

Examples

Example 1: Edit in place a dataset using the default black color as the color of the collar

```
$ gdal raster clean-collar --update my.tif
```

Example 2: Create a new dataset, using black or white as the color of the collar, considering values in the [0,5] range as being considered black, and values in the [250,255] range to be white. It also adds an alpha band to the output dataset.

```
$ gdal raster clean-collar --add-alpha --color=black --color=white --color-threshold=5␣
↪in.tif out.tif
```

5.1.3.8 gdal raster clip

Added in version 3.11.

```

Description

gdal raster clip can be used to clip a raster dataset using georeferenced coordinates.

Either *--bbox* or *--like* must be specified.

The output dataset is in the same SRS as the input one, and the original resolution is preserved. Bounds are rounded to match whole pixel locations (i.e. there is no resampling involved)

`clip` can also be used as a step of *gdal raster pipeline*.

Program-Specific Options

--add-alpha

Adds an alpha mask band to the destination when the source raster has none.

--allow-bbox-outside-source

If set, allows the bounds indicated by *--bbox* to cover an extent that is greater than the input dataset. Output pixels from areas beyond the input extent will be set to zero or the NoData value of the input dataset.

--bbox <xmin>,<ymin>,<xmax>,<ymax>

Bounds to which to clip the dataset. They are assumed to be in the CRS of the input dataset, unless *--bbox-crs* is specified. The X and Y axis are the "GIS friendly ones", that is X is longitude or easting, and Y is latitude or northing. The bounds are expanded if necessary to match input pixel boundaries. By default, **gdal raster clip** will produce an error if the bounds indicated by *--bbox* are greater than the extents of input dataset. This check can be bypassed using *--allow-bbox-outside-source*.

--bbox-crs <CRS>

CRS in which the <xmin>,<ymin>,<xmax>,<ymax> values of *--bbox* are expressed. If not specified, it is assumed to be the CRS of the input dataset. Note that specifying *--bbox-crs* does not cause the raster to be reprojected. Instead, the bounds are reprojected from the bbox-crs to the CRS of the input dataset.

--geometry <WKT_or_GeoJSON>

Geometry as a WKT or GeoJSON string of a polygon (or multipolygon) to which to clip the dataset. Raster areas within the bounding box of the geometry but not inside the geometry itself will be set to the nodata value of the raster, or 0 if there is none. All pixels overlapping the geometry will be selected. If the input geometry is GeoJSON, its CRS is assumed to be WGS84, unless there is a CRS defined in the GeoJSON geometry or *--geometry-crs* is specified. If the input geometry is WKT, its CRS is assumed to be the one of the input dataset, unless *--geometry-crs* is specified. The X and Y axis are the "GIS friendly ones", that is X is longitude or easting, and Y is latitude or northing. Mutually exclusive with *--bbox* and *--like*.

--geometry-crs <CRS>

CRS in which the coordinates values of *--geometry* are expressed. If not specified, it is assumed to be the CRS of the input dataset. The bounds are reprojected from the geometry-crs to the CRS of the input dataset.

--like <DATASET>

Vector or raster dataset to use as a template for bounds. If the specified dataset is a raster, its rectangular bounds are used as the clipping geometry. If the specified dataset is a vector dataset, its polygonal geometries are unioned together to form the clipping geometry. If several layers are present, *--like-sql* or *--like-layer* must be specified. Raster areas within the bounding box of the geometry but not inside the geometry itself will be set to the nodata value of the raster, or 0 if there is none. Mutually exclusive with *--bbox* and *--geometry*.

--like-layer <LAYER-NAME>

Select the named layer from the vector clip dataset. Mutually exclusive with *--like-sql*

--like-sql <SELECT-STATEMENT>

Select desired geometries from the vector clip dataset using an SQL query. e.g `SELECT geom FROM my_layer WHERE country = 'France'`. The SQL dialect used will be the default one of the `like` dataset (OGR SQL for Shapefile, SQLite for GeoPackage, PostgreSQL for PostGIS, etc.). Mutually exclusive with *--like-layer* and *--like-where*

--like-where <WHERE-EXPRESSION>

Restrict desired geometries from vector clip dataset layer based on an attribute query. e.g `country = 'France'`.

--only-bbox

For *--geometry* and *--like*, only consider the bounding box of the geometry.

--window <column>,<line>,<width>,<height>

Added in version 3.12.

Selects a subwindow from the source image for copying based on pixel/line location. Pixel/line offsets (`column` and `line`) are measured from the left and top of the image. If the subwindow extends beyond the bounds of the source dataset, output pixels will be written with a value of zero, unless a NoData value is defined either the source dataset.

Standard Options

--co, --creation-option <NAME>=<VALUE>

Many formats have one or more optional creation options that can be used to control particulars about the file created. For instance, the GeoTIFF driver supports creation options to control compression, and whether the file should be tiled.

May be repeated.

The creation options available vary by format driver, and some simple formats have no creation options at all. A list of options supported for a format can be listed with the *--formats* command line option but the documentation for the format is the definitive source of information on driver creation options. See *Raster drivers* format specific documentation for legal creation options for each format.

--if, --input-format <format>

Format/driver name to be attempted to open the input file(s). It is generally not necessary to specify it, but it can be used to skip automatic driver detection, when it fails to select the appropriate driver. This option can be repeated several times to specify several candidate drivers. Note that it does not force those drivers to open the dataset. In particular, some drivers have requirements on file extensions.

May be repeated.

-f, --of, --format, --output-format <OUTPUT-FORMAT>

Which output raster format to use. Allowed values may be given by `gdal --formats | grep raster | grep rw | sort`

--oo, --open-option <NAME>=<VALUE>

Dataset open option (format specific).

May be repeated.

--overwrite

Allow program to overwrite existing target file or dataset. Otherwise, by default, **gdal** errors out if the target file or dataset already exists.

Return status code

The program returns status code 0 in case of success, and non-zero in case of error (non-blocking errors emitted as warnings are considered as a successful execution).

Examples

Example 1: Clip a GeoTIFF file to the bounding box from longitude 2, latitude 49, to longitude 3, latitude 50 in WGS 84

```
$ gdal raster clip --bbox=2,49,3,50 --bbox-crs=EPSG:4326 in.tif out.tif --overwrite
```

Example 2: Clip a GeoTIFF file using the bounds of reference.tif

```
$ gdal raster clip --like=reference.tif in.tif out.tif --overwrite
```

Example 3: Clip a GeoTIFF file from raster column 1000 and line 2000, for a width of 500 pixels and a height of 600 pixels

```
$ gdal raster clip --window=1000,2000,500,600 in.tif out.tif --overwrite
```

Example 4: Clip a GeoTIFF file using vector features

```
$ gdal raster clip NE2_50M_SR_W.tif clipped.tif \
     --like natural_earth_vector.gpkg \
     --like-layer "ne_50m_admin_0_countries" \
     --like-where "ADMIN='Romania'"
```

Example 5: Clip a GeoTIFF file using SQL

This example produces the same result as *Example 4*, but uses *--like-sql* instead of *--like-layer* and *--like-where*.

The geometry column name (`geom` in this case) must be included in the SQL query.

```
$ gdal raster clip NE2_50M_SR_W.tif clipped.tif \
    --like natural_earth_vector.gpkg \
    --like-sql "SELECT geom FROM ne_50m_admin_0_countries WHERE ADMIN = 'Romania'" \
    --overwrite
```

Example 6: Clip a GeoTIFF using a bounding box extending beyond the source extent, and write the result as a COG

Use `--allow-bbox-outside-source` to suppress the error `ERROR 1: Computed source window -180 2943 6269 6235 falls partially outside source raster extent` when the bounding box exceeds the raster extent.

```
$ gdal raster clip \
    --bbox=3757032.814272985,-626172.1357121654,4383204.9499851465,0 \
    --bbox-crs=EPSG:3857 \
    --allow-bbox-outside-source \
    in.tif out.tif \
    --overwrite \
    --output-format COG
```

5.1.3.9 gdal raster color-map

Added in version 3.11.

Synopsis

```
Usage: gdal raster color-map [OPTIONS] <INPUT> <OUTPUT>

Generate a RGB or RGBA dataset from a single band, using a color map

Positional arguments:
  -i, --input <INPUT>                                    Input raster datasets [required]␣
↪[not available in pipelines]
  -o, --output <OUTPUT>                                  Output raster dataset [required]␣
↪[not available in pipelines]

Common Options:
  -h, --help                                             Display help message and exit
  --json-usage                                           Display usage as JSON document␣
↪and exit
  --config <KEY>=<VALUE>                                 Configuration option [may be␣
↪repeated]
  -q, --quiet                                            Quiet mode (no progress bar or␣
↪warning message) [not available in pipelines]

Options:
  -f, --of, --format, --output-format <OUTPUT-FORMAT>  Output format ("GDALG" allowed)␣
↪[not available in pipelines]

↪[not available in pipelines]
  --oo, --open-option <KEY>=<VALUE>                      Open options [may be repeated]␣
↪[not available in pipelines]
```

Description

gdal raster color-map generates a RGB or RGBA dataset from a single band, using a color map, either attached directly to a raster band, or from an external text file. It is typically used to create hypsometric maps from a DEM.

This subcommand is also available as a potential step of *gdal raster pipeline*

GDALG output (on-the-fly / streamed dataset)

This program supports serializing the command line as a JSON file using the `GDALG` output format. The resulting file can then be opened as a raster dataset using the *GDALG: GDAL Streamed Algorithm* driver, and apply the specified pipeline in a on-the-fly / streamed way.

Program-Specific Options

--add-alpha

Adds an alpha mask band to the output.

-b, --band <BAND>

Index (starting at 1) of the band to process.

--color-map <COLOR-MAP>

Color map filename containing the association between various raster values and the corresponding wished color.

This option must be specified if the input raster band has no attached color table.

The text-based color configuration file generally contains 4 columns per line: the raster value and the corresponding Red, Green, Blue component (between 0 and 255). The raster value can be any floating point value, or the `nv` keyword for the nodata value. The raster can also be expressed as a percentage: 0% being the minimum value found in the raster, 100% the maximum value.

An extra column can be optionally added for the alpha component. If it is not specified, full opacity (255) is assumed.

Various field separators are accepted: comma, tabulation, spaces, ':'.

Common colors used by GRASS can also be specified by using their name, instead of the RGB triplet. The supported list is: white, black, red, green, blue, yellow, magenta, cyan, aqua, grey/gray, orange, brown, purple/violet and indigo.

GMT `.cpt` palette files are also supported (COLOR_MODEL = RGB only).

Note: the syntax of the color configuration file is derived from the one supported by GRASS r.colors utility. ESRI HDR color table files (.clr) also match that syntax. The alpha component and the support of tab and comma as separators are GDAL specific extensions.

For example:

```
3500   white
2500   235:220:175
50%   190 185 135
700    240 250 150
0      50  180  50
nv     0   0   0   0
```

To implement a "round to the floor value" mode, the raster value can be duplicate with a new value being slightly above the threshold. For example to have red in [0,10], green in]10,20] and blue in]20,30]:

```
0       red
10      red
10.001  green
20      green
20.001  blue
30      blue
```

--color-selection `interpolate|exact|nearest`

How to compute output colors from input values:

- `interpolate` (default): apply linear interpolation when a raster value falls between two entries of the color map.
- `exact`: only input raster values matching exacting an entry of the color map will be colorized. If none matching color entry is found, the "0,0,0,0" RGBA quadruplet will be used.
- `nearest`: input raster values will be assigned the entry of the color map that is the closest.

> **Note**
>
> This option is only taken into account when *--color-map* is specified.

Standard Options

--co, --creation-option `<NAME>=<VALUE>`

Many formats have one or more optional creation options that can be used to control particulars about the file created. For instance, the GeoTIFF driver supports creation options to control compression, and whether the file should be tiled.

May be repeated.

The creation options available vary by format driver, and some simple formats have no creation options at all. A list of options supported for a format can be listed with the *--formats* command line option but the documentation for the format is the definitive source of information on driver creation options. See *Raster drivers* format specific documentation for legal creation options for each format.

-f, --of, --format, --output-format `<OUTPUT-FORMAT>`

Which output raster format to use. Allowed values may be given by `gdal --formats | grep raster | grep rw | sort`

--overwrite

Allow program to overwrite existing target file or dataset. Otherwise, by default, **gdal** errors out if the target file or dataset already exists.

Return status code

The program returns status code 0 in case of success, and non-zero in case of error (non-blocking errors emitted as warnings are considered as a successful execution).

Examples

Example 1: Generates a RGB dataset from a DTED0 file using an external color map

```
$ gdal raster color-map --color-map=color-map.txt n43.dt0 out.tif --overwrite
```

5.1.3.10 gdal raster contour

Added in version 3.11.

Synopsis

```
Usage: gdal raster contour [OPTIONS] <INPUT> <OUTPUT>

Creates a vector contour from a raster elevation model (DEM).

Positional arguments:
  -i, --input <INPUT>                                   Input raster datasets [required]␣

```

Description

gdal raster contour creates a vector contour from a raster elevation model (DEM).

Since GDAL 3.12, this algorithm can be part of a *gdal pipeline*.

Added in version 3.12.

GDALG output (on-the-fly / streamed dataset)

This program supports serializing the command line as a JSON file using the `GDALG` output format. The resulting file can then be opened as a vector dataset using the *GDALG: GDAL Streamed Algorithm* driver, and apply the specified pipeline in a on-the-fly / streamed way.

> **Note**
>
> However this algorithm is not natively streaming compatible. Consequently a in-memory temporary dataset will be generated, which may cause significant processing time at opening.

Program-Specific Options

--3d

Forces the production of 3D vectors instead of 2D. Includes elevation at every vertex.

-b, --band <BAND>

Picks a particular band to get the DEM from. Defaults to band 1.

--elevation-name <ELEVATION-NAME>

Provides a name for the attribute in which to put the elevation. If not provided no elevation attribute is attached. Ignored in polygonal contouring (-p) mode.

-e, --exp-base <EXP-BASE>

Generate levels on an exponential scale: base ^ k, for k an integer. Mutually exclusive with *--interval*, *--levels*.

--group-transactions <GROUP-TRANSACTIONS>

Group n features per transaction (default 100 000).

--interval <INTERVAL>

Elevation interval between contours. Mutually exclusive with *--levels*, *--exp-base*. The first contour will be generated at the first multiple of INTERVAL which is greater than the raster minimum value.

--levels <LEVELS>

List of contour levels. *MIN* and *MAX* are special values that represent the minimum and maximum values in the raster. When *--polygonize* is used, the specified values are used as bounds of the generated polygons. Mutually exclusive with *--interval*, *--exp-base*.

--max-name <MAX-NAME>

Provides a name for the attribute in which to put the maximum elevation. If not provided no maximum elevation attribute is attached. Ignored in polygonal contouring (-p) mode.

--min-name <MIN-NAME>

Provides a name for the attribute in which to put the minimum elevation. If not provided no minimum elevation attribute is attached. Ignored in polygonal contouring (-p) mode.

--off, --offset <OFFSET>

Offset from zero relative to which to interpret intervals.

--nln, --output-layer <OUTPUT-LAYER>

Provides a name for the output vector layer. Defaults to "contour".

-p, --polygonize

Create polygons instead of lines.

--input-nodata <INPUT-NODATA>

Input pixel value to treat as 'nodata'.

Standard Options

--co, --creation-option <NAME>=<VALUE>

Many formats have one or more optional creation options that can be used to control particulars about the file created. For instance, the GeoTIFF driver supports creation options to control compression, and whether the file should be tiled.

May be repeated.

The creation options available vary by format driver, and some simple formats have no creation options at all. A list of options supported for a format can be listed with the *--formats* command line option but the documentation for the format is the definitive source of information on driver creation options. See *Raster drivers* format specific documentation for legal creation options for each format.

--if, --input-format <format>

Format/driver name to be attempted to open the input file(s). It is generally not necessary to specify it, but it can be used to skip automatic driver detection, when it fails to select the appropriate driver. This option can be repeated several times to specify several candidate drivers. Note that it does not force those drivers to open the dataset. In particular, some drivers have requirements on file extensions.

May be repeated.

--lco, --layer-creation-option <NAME>=<VALUE>

Many formats have one or more optional layer creation options that can be used to control particulars about the layer created. For instance, the GeoPackage driver supports layer creation options to control the feature identifier or geometry column name, setting the identifier or description, etc.

May be repeated.

The layer creation options available vary by format driver, and some simple formats have no layer creation options at all. A list of options supported for a format can be listed with the *--formats* command line option but the documentation for the format is the definitive source of information on driver creation options. See *Vector drivers* format specific documentation for legal creation options for each format.

Note that layer creation options are different from dataset creation options.

--oo, --open-option <NAME>=<VALUE>

Dataset open option (format specific).

May be repeated.

--output-open-option, --output-oo <NAME>=<VALUE>

Added in version 3.12.

Dataset open option for output dataset (format specific).

May be repeated.

-f, --of, --format, --output-format <OUTPUT-FORMAT>

Which output vector format to use. Allowed values may be given by `gdal --formats | grep vector | grep rw | sort`

--overwrite

Allow program to overwrite existing target file or dataset. Otherwise, by default, **gdal** errors out if the target file or dataset already exists.

Return status code

The program returns status code 0 in case of success, and non-zero in case of error (non-blocking errors emitted as warnings are considered as a successful execution).

Examples

Example 1: Create contour lines from a raster elevation model

The following example creates contour lines from a raster elevation model:

```
gdal raster contour --interval 100 elevation.tif contour.shp
```

This will create a shapefile named `contour.shp` with contour lines at 100 meter intervals.

Example 2: Create contour polygons from a raster elevation model with custom attributes and fixed levels

The following example creates contour polygons from a raster elevation model with custom attributes and fixed levels:

```
gdal raster contour --levels MIN,100,200,MAX --polygonize --min-name MIN --max-
↪name MAX elevation.tif contour.shp
```

This will create a shapefile named `contour.shp` with contour polygons from the minimum raster value to 100, and from 100 to 200 and from 200 to the maximum value, and with attributes `MIN`, and `MAX`.

5.1.3.11 gdal raster compare

Added in version 3.12.

Synopsis

```
Usage: gdal raster compare [OPTIONS] <REFERENCE> <INPUT>

Compare two raster datasets.

Positional arguments:
  --reference <REFERENCE>              Reference dataset [required]
  -i, --input <INPUT>                  Input raster dataset [required] [not available in␣
↪pipelines]

Common Options:
  -h, --help                           Display help message and exit
  --json-usage                         Display usage as JSON document and exit
  --config <KEY>=<VALUE>               Configuration option [may be repeated]
  -q, --quiet                          Quiet mode (no progress bar or warning message)␣
↪[not available in pipelines]

Options:
  --skip-all-optional                  Skip all optional comparisons
  --skip-binary                        Skip binary file comparison
  --skip-crs                           Skip CRS comparison
  --skip-geotransform                  Skip geotransform comparison
  --skip-overview                      Skip overview comparison
  --skip-metadata                      Skip metadata comparison
  --skip-rpc                           Skip RPC metadata comparison
  --skip-geolocation                   Skip Geolocation metadata comparison
  --skip-subdataset                    Skip subdataset comparison

Advanced Options:
  --if, --input-format <INPUT-FORMAT>  Input formats [may be repeated] [not available in␣
↪pipelines]
```

(continues on next page)

(continued from previous page)

```
  --oo, --open-option <KEY>=<VALUE>    Open options [may be repeated] [not available in␣
↪pipelines]
```

Description

gdal raster compare compares two GDAL supported datasets and reports the differences. In addition to reporting differences to the standard output, the program will also return the difference count in its exit value.

As a convention, the first dataset specified as a positional argument, or through *--reference*, is assumed to be the reference/exact/golden dataset. The second dataset specified as a positional argument, or through *--input*, is the dataset compared to the reference dataset.

Image pixels, and various metadata are checked. There is also a byte by byte comparison done which will count as one difference. So, if it is only important that the GDAL visible data is identical, a difference count of 1 (the binary difference) should be considered acceptable, or you may specify *--skip-binary* to omit byte to byte comparison.

This program can also be used as the last step of a *raster pipeline*.

The following options are available:

Program-Specific Options

--input <input-dataset>

The dataset being compared to the reference dataset, referred to as the input dataset.

--reference <reference-dataset>

The dataset that is considered correct, referred to as the reference dataset.

--skip-all-optional

Whether to skip all optional tests. This is an alias to defining all other `--skip-XXXX` options.

The remaining non-optional tests are:

- checking dataset width, height and band count
- checking band description, data type, color interpretation and nodata value
- checking pixel content

--skip-binary

Whether to skip exact comparison of binary content.

--skip-crs

Whether to skip comparison of coordinate reference systems (CRS).

--skip-geolocation

Whether to skip comparison of GEOLOCATION metadata domain.

--skip-geotransform

Whether to skip comparison of geotransform matrix.

--skip-metadata

Whether to skip comparison of metadata

--skip-overview

Whether to skip comparison of overviews.

--skip-rpc

Whether to skip comparison of Rational Polynomial Coefficients (RPC) metadata domain.

--skip-subdataset

Whether to ignore comparison of all subdatasets that are part of the dataset.

Standard Options

--if, --input-format <format>

Format/driver name to be attempted to open the input file(s). It is generally not necessary to specify it, but it can be used to skip automatic driver detection, when it fails to select the appropriate driver. This option can be repeated several times to specify several candidate drivers. Note that it does not force those drivers to open the dataset. In particular, some drivers have requirements on file extensions.

May be repeated.

--oo, --open-option <NAME>=<VALUE>

Dataset open option (format specific).

May be repeated.

Return status code

The program returns status code 0 in case of success, and non-zero in case of error (non-blocking errors emitted as warnings are considered as a successful execution).

Examples

Example 1: Comparing two datasets that differ by their data types

```
$ gdal raster compare autotest/gcore/data/byte.tif autotest/gcore/data/uint16.tif
Reference file has size 736 bytes, whereas input file has size 1136 bytes.
Reference band 1 has data type Byte, but input band has data type UInt16

$ echo $?
2
```

Example 2: Comparing two datasets while values have different units

```
$ gdal raster pipeline read test_in_foot.tif ! calc --calc "X * 0.3048" ! compare --
↪reference=reference_in_meter.tif
```

5.1.3.12 gdal raster convert

Added in version 3.11.

Synopsis

```
Usage: gdal raster convert [OPTIONS] <INPUT> <OUTPUT>

Convert a raster dataset.

↪[not available in pipelines]
```

Description

gdal raster convert can be used to convert raster data between different formats.

Standard Options

--append

Append input raster as a new subdataset to an existing output file. Only works with drivers that support adding subdatasets such as *GTiff -- GeoTIFF File Format* and *GPKG -- GeoPackage raster* This also creates the output dataset if it does not exist yet.

--co, --creation-option <NAME>=<VALUE>

Many formats have one or more optional creation options that can be used to control particulars about the file created. For instance, the GeoTIFF driver supports creation options to control compression, and whether the file should be tiled.

May be repeated.

The creation options available vary by format driver, and some simple formats have no creation options at all. A list of options supported for a format can be listed with the *--formats* command line option but the documentation

for the format is the definitive source of information on driver creation options. See *Raster drivers* format specific documentation for legal creation options for each format.

--if, --input-format <format>

Format/driver name to be attempted to open the input file(s). It is generally not necessary to specify it, but it can be used to skip automatic driver detection, when it fails to select the appropriate driver. This option can be repeated several times to specify several candidate drivers. Note that it does not force those drivers to open the dataset. In particular, some drivers have requirements on file extensions.

May be repeated.

--oo, --open-option <NAME>=<VALUE>

Dataset open option (format specific).

May be repeated.

-f, --of, --format, --output-format <OUTPUT-FORMAT>

Which output raster format to use. Allowed values may be given by `gdal --formats | grep raster | grep rw | sort`

--overwrite

Allow program to overwrite existing target file or dataset. Otherwise, by default, **gdal** errors out if the target file or dataset already exists.

-q, --quiet

Suppress progress bar and some warning messages.

Return status code

The program returns status code 0 in case of success, and non-zero in case of error (non-blocking errors emitted as warnings are considered as a successful execution).

Examples

Example 1: Converting file utm.tif to a cloud-optimized GeoTIFF using JPEG compression

```
$ gdal raster convert --format=COG --co COMPRESS=JPEG utm.tif utm_cog.tif
```

Example 2: Converting file utm.tif to GeoPackage raster

```
$ gdal raster convert utm.tif utm.gpkg
```

5.1.3.13 gdal raster create

Added in version 3.11.

Synopsis

```
Usage: gdal raster create [OPTIONS] <OUTPUT>

Create a new raster dataset.

Positional arguments:
  -o, --output <OUTPUT>                                    Output raster dataset␣
```

↪repeated] [not available in pipelines]
```

Description

gdal raster create can be used to initialize a new raster file, from its dimensions, band count, CRS, geotransform, nodata value and metadata.

The new file can also be initialized from a model input file with the optional *--like* option, copying its properties but not its pixel values. By default, metadata and the overview structure are not copied from the model input file, unless *--copy-metadata* and *--copy-overviews* are specified. Options *--size*, *--band-count*, *--datatype*, *--nodata*, *--crs*, *--bbox*, *--metadata* can be used to override the values inherited from the model input file.

For GeoTIFF output, setting the `SPARSE_OK` creation option to `YES` can be useful to create a file of minimum size.`

gdal raster create can be used also in special cases, like creating a PDF file from a XML composition file.

Since GDAL 3.13, `create` can also be used as a step of *gdal raster pipeline*.

Program-Specific Options

--band-count <count>

Number of bands. Defaults to 1.

--bbox <xmin>,<ymin>,<xmax>,ymax>

Sets the spatial bounding box, in CRS units. 'x' is longitude values for geographic CRS and easting for projected CRS. 'y' is latitude values for geographic CRS and northing for projected CRS.

--burn <value>

A fixed value to burn into a band. A list of *--burn* options can be supplied, one per band (the first value will apply to the first band, the second one to the second band, etc.). If a single value is specified, it will apply to all bands.

--copy-metadata

Copy metadata from input dataset and raster bands. Requires *--like* to be specified.

--copy-overviews

Create same overview levels as input dataset (but with empty content). Requires *--like* to be specified.

--crs <CRS>

Set CRS.

The coordinate reference systems that can be passed are anything supported by the *OGRSpatialReference::SetFromUserInput()* call, which includes EPSG Projected, Geographic or Compound CRS (i.e. EPSG:4296), a well known text (WKT) CRS definition, PROJ.4 declarations, or the name of a .prj file containing a WKT CRS definition.

`null` or `none` can be specified to unset the existing CRS of the *--like* dataset if it is set.

Note that the spatial extent is also left unchanged.

-i, --like, --input <TEMPLATE-DATASET>

Name of GDAL input dataset that serves as a template for default values of options *--size*, *--band-count*, *--datatype*, *--crs*, *--bbox* and *--nodata*. Note that the pixel values will *not* be copied.

Since GDAL 3.13, if the input dataset is tiled, and for output formats `GTiff`, `COG` and `GPKG`, its tile dimensions are replicated to the output file, when they are compatible with its capabilities, and if the user hasn't specified any creation option related to tiling.

--metadata <KEY>=<VALUE>

Adds a metadata item, at the dataset level.

--nodata <value>

Sets the nodata value.

null or none can be specified to unset the existing nodata value of the *--like* dataset if it is set. nan, inf or -inf are also accepted for floating point rasters to respectively mean the special values not-a-number, positive infinity and minus infinity.

--size <xsize>,<ysize>

Set the size of the output file in pixels. First value is width. Second one is height.

Standard Options

--append

Append input raster as a new subdataset to an existing output file. Only works with drivers that support adding subdatasets such as *GTiff -- GeoTIFF File Format* and *GPKG -- GeoPackage raster* This also creates the output dataset if it does not exist yet.

--co, --creation-option <NAME>=<VALUE>

Many formats have one or more optional creation options that can be used to control particulars about the file created. For instance, the GeoTIFF driver supports creation options to control compression, and whether the file should be tiled.

May be repeated.

The creation options available vary by format driver, and some simple formats have no creation options at all. A list of options supported for a format can be listed with the *--formats* command line option but the documentation for the format is the definitive source of information on driver creation options. See *Raster drivers* format specific documentation for legal creation options for each format.

--if, --input-format <format>

Format/driver name to be attempted to open the input file(s). It is generally not necessary to specify it, but it can be used to skip automatic driver detection, when it fails to select the appropriate driver. This option can be repeated several times to specify several candidate drivers. Note that it does not force those drivers to open the dataset. In particular, some drivers have requirements on file extensions.

May be repeated.

--oo, --open-option <NAME>=<VALUE>

Dataset open option (format specific).

May be repeated.

--ot, --datatype, --output-data-type <OUTPUT-DATA-TYPE>

Output data type among Byte, Int8, UInt16, Int16, UInt32, Int32, UInt64, Int64, CInt16, CInt32, Float32, Float64, CFloat32, CFloat64.

-f, --of, --format, --output-format <OUTPUT-FORMAT>

Which output raster format to use. Allowed values may be given by gdal --formats | grep raster | grep + | sort

--overwrite

Allow program to overwrite existing target file or dataset. Otherwise, by default, **gdal** errors out if the target file or dataset already exists.

Return status code

The program returns status code 0 in case of success, and non-zero in case of error (non-blocking errors emitted as warnings are considered as a successful execution).

Examples

Example 1: Initialize a new GeoTIFF file with 3 bands and a uniform value of 10

```
gdal raster create --size=20,20 --band-count=3 --crs=EPSG:4326 --bbox=2,49,3,50 --burn␣
↪10 out.tif
```

Example 2: Create a PDF file from a XML composition file

```
gdal raster create --creation-option COMPOSITION_FILE=composition.xml out.pdf
```

Example 3: Initialize a blank GeoTIFF file from an input one

```
gdal raster create --like prototype.tif output.tif
```

5.1.3.14 gdal raster edit

Added in version 3.11.

Synopsis

```
Usage: gdal raster edit [OPTIONS] <DATASET>

Edit a raster dataset.

Positional arguments:
  --dataset <DATASET>                                       Dataset (to be updated in-
↪place, unless --auxiliary) [required] [not available in pipelines]

Common Options:
  -h, --help                                                Display help message and␣

↪repeated] [not available in pipelines]
```

Description

gdal raster edit can be used to edit a raster dataset.

This subcommand is also available as a potential step of *gdal raster pipeline*

Program-Specific Options

--approx-stats

Compute raster band statistics for all bands. They may be computed based on overviews or a subset of all tiles. Useful if you are in a hurry and don't need precise stats.

> **Note**
>
> This option is not available when the command is part of a pipeline.

--auxiliary

Force opening the dataset in read-only mode. For drivers that implement the Persistent Auxiliary Metadata (PAM) mechanism, changes will be saved in an auxiliary side car file of extension `.aux.xml`.

-b, --band <BAND>

Added in version 3.13.

Index (starting at 1) of the band to which the following options apply: *--color-map*, *--unset-color-table*. Defaults to one if not specified.

--bbox <xmin>,<ymin>,<xmax>,ymax>

Override the spatial bounding box, in CRS units, without reprojecting or subsetting. 'x' is longitude values for geographic CRS and easting for projected CRS. 'y' is latitude values for geographic CRS and northing for projected CRS.

--color-map <COLOR-MAP>

Added in version 3.13.

Color map filename containing the association between various raster values and the corresponding wished color to set on the first band, or the one specified by *--band*. This can be either a GDAL dataset with a color table attached to its first band or a text-based color configuration

The text-based color configuration file generally contains 4 columns per line: the raster value and the corresponding Red, Green, Blue component (between 0 and 255). The raster value mus be an integer value between 0 and 65535. The raster value can also be expressed as a percentage: 0% being the minimum value found in the raster, 100% the maximum value.

An extra column can be optionally added for the alpha component. If it is not specified, full opacity (255) is assumed.

Various field separators are accepted: comma, tabulation, spaces, ':'.

Common colors used by GRASS can also be specified by using their name, instead of the RGB triplet. The supported list is: white, black, red, green, blue, yellow, magenta, cyan, aqua, grey/gray, orange, brown, purple/violet and indigo.

GMT `.cpt` palette files are also supported (COLOR_MODEL = RGB only).

Note: the syntax of the color configuration file is derived from the one supported by GRASS r.colors utility. ESRI HDR color table files (.clr) also match that syntax. The alpha component and the support of tab and comma as separators are GDAL specific extensions.

For example:

```
3500   white
2500   235:220:175
50%   190 185 135
700    240 250 150
0      50  180  50
```

--crs <CRS>

Override CRS, without reprojecting.

The coordinate reference systems that can be passed are anything supported by the *OGRSpatialReference::SetFromUserInput()* call, which includes EPSG Projected, Geographic or

Compound CRS (i.e. EPSG:4296), a well known text (WKT) CRS definition, PROJ.4 declarations, or the name of a .prj file containing a WKT CRS definition.

`null` or `none` can be specified to unset an existing CRS.

Note that the spatial extent is also left unchanged.

--dataset <DATASET>

Dataset name, to be updated in-place, unless *--auxiliary* is set. Required.

--gcp <GCP>

Added in version 3.12.

Set ground control point(s), replacing any existing GCPs. Each GCP must be formatted as a string "pixel,line,easting,northing" or "pixel,line,easting,northing,elevation". Each GCP must be specified with a `--gcp` argument.

It is also possible to provide a single `--gcp` argument whose value is the filename of a vector dataset, prefixed with `@`. This dataset must have a single layer with the following required fields `column`, `line`, `x`, `y`, and optionally `id`, `info` and `z`.

--hist

Compute histogram information for all bands.

> **Note**
>
> This option is not available when the command is part of a pipeline.

--color-interpretation [all|<BAND>=]<COLOR-INTERPRETATION>

Added in version 3.13.

Set band color interpretation. May be repeated.

<COLOR-INTERPRETATION> is one of `red`, `green`, `blue`, `alpha`, `gray`, `undefined`, `pan`, `coastal`, `rededge`, `nir`, `swir`, `mwir` or `lwir`.

Several syntaxes are supported:

- specifying `all=`<COLOR-INTERPRETATION>: set the color interpretation on all bands.
- specifying as many <COLOR-INTERPRETATION> as there are bands, starting from band 1 to the last band.
- specifying the color interpretation on a subset of bands with <BAND>=<COLOR-INTERPRETATION> where band is the band number starting at 1.

--scale [<BAND>=]<SCALE>

Added in version 3.13.

Set band scale factor. May be repeated.

Several syntaxes are supported:

- specifying one single <SCALE>: set the scale on all bands.
- specifying as many <SCALE> as there are bands, starting from band 1 to the last band.
- specifying the scale on a subset of bands with <BAND>=<SCALE> where band is the band number starting at 1.

--offset [<BAND>=]<OFFSET>

Added in version 3.13.

Set band offset constant. May be repeated.

Several syntaxes are supported:

- specifying one single <OFFSET>: set the offset on all bands.
- specifying as many <OFFSET> as there are bands, starting from band 1 to the last band.
- specifying the offset on a subset of bands with <BAND>=<OFFSET> where band is the band number starting at 1.

--metadata <KEY>=<VALUE>

Add/update metadata item, at the dataset level. May be repeated.

--nodata <value>

Override nodata value.

`null` or `none` can be specified to unset an existing nodata value.

--stats

Compute raster band statistics for all bands.

--unset-color-table

Added in version 3.13.

Remove the color table associated to the first band, or the one specified by *--band*.

--unset-metadata <KEY>

Remove metadata item, at the dataset level. May be repeated.

--unset-metadata-domain <DOMAIN>

Added in version 3.12.

Remove metadata domain, at the dataset level. May be repeated.

Standard Options

--oo, --open-option <NAME>=<VALUE>

Dataset open option (format specific).

May be repeated.

Return status code

The program returns status code 0 in case of success, and non-zero in case of error (non-blocking errors emitted as warnings are considered as a successful execution).

Examples

Example 1: Override (without reprojecting) the CRS of a dataset

```
$ gdal raster edit --crs=EPSG:32632 my.tif
```

Example 2: Override (without reprojecting or subsetting) the bounding box of a dataset

```
$ gdal raster edit --bbox=2,49,3,50 my.tif
```

Example 3: Add a metadata item

```
$ gdal raster edit --metadata AUTHOR=EvenR my.tif
```

Example 4: Remove a metadata item

```
$ gdal raster edit --unset-metadata AUTHOR my.tif
```

Example 5: Add 2 ground control point (GCP) for (column=0,line=0,X=2,Y=49) and (column=50,line=100,X=3,Y=48)

```
$ gdal raster edit --gcp 0,0,2,49 --gcp 50,100,3,48 my.tif
```

Example 6: Add ground control point (GCP) from gcps.csv, that must have fields named column, line, x and y.

```
$ gdal raster edit --gcp @gcps.csv my.tif
```

Example 7: Set red, green, blue, NIR color interpretation to a 4-band dataset

```
$ gdal raster edit --color-interpretation red,green,blue,nir 4band.tif
```

5.1.3.15 gdal raster footprint

Added in version 3.11.

Synopsis

```
Usage: gdal raster footprint [OPTIONS] <INPUT>... <OUTPUT>

Compute the footprint of a raster dataset.

Positional arguments:
  -i, --input <INPUT>                                    Input raster datasets [may be␣

```

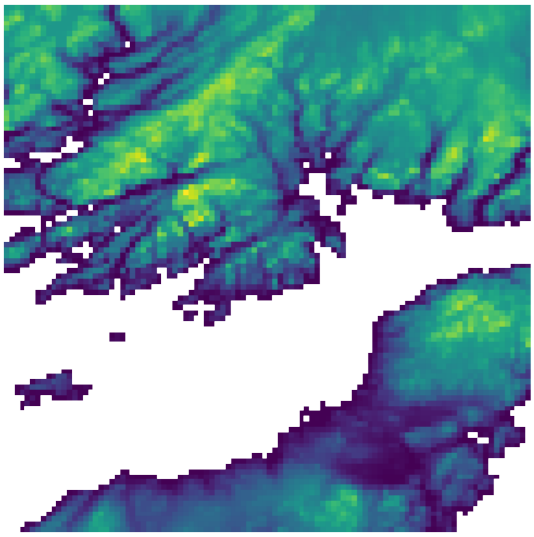
Description

gdal raster footprint computes the footprint of a raster file, taking into account nodata values (or more generally the mask band attached to the raster bands), and generating polygons/multipolygons corresponding to areas where pixels are valid, and write to an output vector file.

Since GDAL 3.12, this algorithm can be part of a *gdal pipeline*.

The **gdal raster clean-collar** utility may be run as a pre-processing step to generate proper mask bands.



Example footprint calculated with default options of **gdal raster footprint**.

Post-vectorization geometric operations are applied in the following order:

- optional splitting (*--split-multipolygons*)
- optional densification (*--densify-distance*)
- optional reprojection (*--output-crs*)
- optional filtering by minimum ring area (*--min-ring-area*)
- optional application of convex hull (*--convex-hull*)
- optional simplification (*--simplify-tolerance*)
- limitation of number of points (*--max-points*)

Added in version 3.12.

GDALG output (on-the-fly / streamed dataset)

This program supports serializing the command line as a JSON file using the `GDALG` output format. The resulting file can then be opened as a vector dataset using the *GDALG: GDAL Streamed Algorithm* driver, and apply the specified pipeline in a on-the-fly / streamed way.

> **Note**
>
> However this algorithm is not natively streaming compatible. Consequently a in-memory temporary dataset will be generated, which may cause significant processing time at opening.

Program-Specific Options

--absolute-path

Enables writing the absolute path of the input dataset. By default, the filename is written in the location field exactly as specified on the command line.

-b, --band <band>

Select an input <band> to be processed. Bands are numbered from 1. Multiple *-b* switches may be used to select a set of input bands. If not specified, all bands are taken into account. The way multiple bands are combined is controlled by *--combine-bands*

--combine-bands `union|intersection`

Defines how the mask bands of the selected bands are combined to generate a single mask band, before being vectorized. The default value is `union`: that is a pixel is valid if it is valid at least for one of the selected bands. `intersection` means that a pixel is valid only if it is valid for all selected bands.

--coordinate-system `pixel|georeferenced`

Target coordinate system. By default if the input dataset is georeferenced, `georeferenced` is implied, that is the footprint geometry will be expressed as coordinates in the CRS of the raster (or the one specified with *--output-crs*). If specifying `pixel`, the coordinates of the footprint geometry are column and line indices.

--convex-hull

When specified, the convex hull of (multi)polygons is computed.

--densify-distance <value>

The specified value of this option is the maximum distance between 2 consecutive points of the output geometry. The unit of the distance is in pixels if *--coordinate-system* equals `pixel`, or otherwise in georeferenced units of the source raster. This option is applied before the reprojection implied by *--output-crs*.

--input-nodata <value>

Set nodata values for input bands (different values can be supplied for each band). If a single value is specified, it applies to all selected bands. If more than one value is supplied, there should be as many values as the number of selected bands, and all values should be quoted to keep them together as a single operating system argument. If the option is not specified, the intrinsic mask band of each selected bands will be used.

--location-field <field_name>

Specifies the name of the field in the resulting vector dataset where the path of the input dataset will be stored. The default field name is "location". To prevent writing the path of the input dataset, use *--no-location-field*

--max-points <value>|`unlimited`

Maximum number of points of each output geometry (not counting the closing point of each ring, which is always identical to the first point). The default value is 100. `unlimited` can be used to remove that limitation.

--min-ring-area <value>

Minimum value for the area of a ring The unit of the area is in square pixels if *--coordinate-system* equals `pixel`, or otherwise in georeferenced units of the target vector dataset. This option is applied after the reprojection implied by *--output-crs*

--no-location-field

Turns off the writing of the path of the input dataset as a field in the output vector dataset.

--output-crs <CRS_DEF>

Target CRS of the output file. The <CRS_DEF> may be any of the usual GDAL/OGR forms, complete WKT, PROJ.4, EPSG:n or a file containing the WKT. Specifying this option implies `--coordinate-system=georeferenced`. The footprint is reprojected from the CRS of the source raster to the specified CRS.

--output-layer <OUTPUT-LAYER>

Output layer name. Defaults to `footprint`.

--overview <index>

To specify which overview level of source file must be used, when overviews are available on the source raster. By default the full resolution level is used. The index is 0-based, that is 0 means the first overview level. This option is mutually exclusive with *--input-nodata*.

--simplify-tolerance <value>

The specified value of this option is the tolerance used to merge consecutive points of the output geometry using the *OGRGeometry::Simplify()* method. The unit of the distance is in pixels if *--coordinate-system* equals `pixel`, or otherwise in georeferenced units of the target vector dataset. This option is applied after the reprojection implied by *--output-crs*.

--split-multipolygons

When specified, multipolygons are split as several features each with one single polygon.

Standard Options

--append

Whether appending features to existing layer(s) is allowed. This also creates the output dataset if it does not exist yet.

--co, --creation-option <NAME>=<VALUE>

Many formats have one or more optional creation options that can be used to control particulars about the file created. For instance, the GeoTIFF driver supports creation options to control compression, and whether the file should be tiled.

May be repeated.

The creation options available vary by format driver, and some simple formats have no creation options at all. A list of options supported for a format can be listed with the *--formats* command line option but the documentation for the format is the definitive source of information on driver creation options. See *Raster drivers* format specific documentation for legal creation options for each format.

--if, --input-format <format>

Format/driver name to be attempted to open the input file(s). It is generally not necessary to specify it, but it can be used to skip automatic driver detection, when it fails to select the appropriate driver. This option can be repeated several times to specify several candidate drivers. Note that it does not force those drivers to open the dataset. In particular, some drivers have requirements on file extensions.

May be repeated.

--lco, --layer-creation-option <NAME>=<VALUE>

Many formats have one or more optional layer creation options that can be used to control particulars about the layer created. For instance, the GeoPackage driver supports layer creation options to control the feature identifier or geometry column name, setting the identifier or description, etc.

May be repeated.

The layer creation options available vary by format driver, and some simple formats have no layer creation options at all. A list of options supported for a format can be listed with the *--formats* command line option but the documentation for the format is the definitive source of information on driver creation options. See *Vector drivers* format specific documentation for legal creation options for each format.

Note that layer creation options are different from dataset creation options.

--oo, --open-option <NAME>=<VALUE>

Dataset open option (format specific).

May be repeated.

-f, --of, --format, --output-format <OUTPUT-FORMAT>

Which output vector format to use. Allowed values may be given by `gdal --formats | grep vector | grep rw | sort`

--overwrite

Allow program to overwrite existing target file or dataset. Otherwise, by default, **gdal** errors out if the target file or dataset already exists.

Return status code

The program returns status code 0 in case of success, and non-zero in case of error (non-blocking errors emitted as warnings are considered as a successful execution).

Examples

Example 1: Write the footprint of a GeoTIFF file into a GeoJSON file.

```
gdal raster footprint my_raster.tif footprint.geojson
```

5.1.3.16 gdal raster fill-nodata

Added in version 3.11.

Synopsis

```
Usage: gdal raster fill-nodata [OPTIONS] <INPUT> <OUTPUT>

Fill nodata raster regions by interpolation from edges.

↪[not available in pipelines]
```

Description

gdal raster fill-nodata fills nodata areas by interpolating from valid pixels around the edges of the area.

This subcommand is also available as a potential step of *gdal raster pipeline* (since GDAL 3.12)

Added in version 3.12.

GDALG output (on-the-fly / streamed dataset)

This program supports serializing the command line as a JSON file using the `GDALG` output format. The resulting file can then be opened as a raster dataset using the *GDALG: GDAL Streamed Algorithm* driver, and apply the specified pipeline in a on-the-fly / streamed way.

> **Note**
>
> However this algorithm is not natively streaming compatible. Consequently a temporary dataset will be generated, which may cause significant processing time at opening.

Program-Specific Options

-b, --band <BAND>

Select an input <BAND> to be processed. Bands are numbered from 1. Default is the first band of the input dataset.

--mask <MASK>

Use the first band of the specified file as a validity mask (zero is invalid, non-zero is valid).

--max-distance <MAX_DISTANCE>

Specifies the maximum distance (in pixels) that the algorithm will search out for values to interpolate. Default is 100 pixels.

--smoothing-iterations <SMOOTHING_ITERATIONS>

Specifies the number of smoothing iterations to apply to the filled raster. This can help to reduce artifacts in the filled areas. Default is 0 iterations.

--strategy <STRATEGY>

Select the interpolation <STRATEGY> to use. By default, pixels are interpolated using an inverse distance weighting (*invdist*). It is also possible to choose a nearest neighbour (*nearest*) strategy.

Standard Options

--append

Append input raster as a new subdataset to an existing output file. Only works with drivers that support adding subdatasets such as *GTiff -- GeoTIFF File Format* and *GPKG -- GeoPackage raster* This also creates the output dataset if it does not exist yet.

--co, --creation-option <NAME>=<VALUE>

Many formats have one or more optional creation options that can be used to control particulars about the file created. For instance, the GeoTIFF driver supports creation options to control compression, and whether the file should be tiled.

May be repeated.

The creation options available vary by format driver, and some simple formats have no creation options at all. A list of options supported for a format can be listed with the *--formats* command line option but the documentation for the format is the definitive source of information on driver creation options. See *Raster drivers* format specific documentation for legal creation options for each format.

--if, --input-format <format>

Format/driver name to be attempted to open the input file(s). It is generally not necessary to specify it, but it can be used to skip automatic driver detection, when it fails to select the appropriate driver. This option can be repeated several times to specify several candidate drivers. Note that it does not force those drivers to open the dataset. In particular, some drivers have requirements on file extensions.

May be repeated.

--oo, --open-option <NAME>=<VALUE>

Dataset open option (format specific).

May be repeated.

-f, --of, --format, --output-format <OUTPUT-FORMAT>

Which output raster format to use. Allowed values may be given by `gdal --formats | grep raster | grep rw | sort`

--overwrite

Allow program to overwrite existing target file or dataset. Otherwise, by default, **gdal** errors out if the target file or dataset already exists.

Return status code

The program returns status code 0 in case of success, and non-zero in case of error (non-blocking errors emitted as warnings are considered as a successful execution).

Examples

Example 1: Fill nodata areas in a raster

The command specifies to use the second band of the input raster, 50 px max distance, 3 smoothing iterations and the *nearest* strategy for interpolation. The output will be saved in *output.tif*.

```
gdal raster fill-nodata -b 2 --max-distance 50 --smoothing-iterations 3 \
    --strategy nearest --mask mask.tif \
    input.tif output.tif
```

5.1.3.17 gdal raster hillshade

Added in version 3.11.

Synopsis

```
Usage: gdal raster hillshade [OPTIONS] <INPUT> <OUTPUT>

```

Description

gdal raster hillshade generates a shaded relief map, from any GDAL-supported elevation raster.

This subcommand is also available as a potential step of *gdal raster pipeline*

It generates an 8-bit raster with a nice shaded relief effect. It is very useful for visualizing the terrain. You can optionally specify the azimuth and altitude of the light source, a vertical exaggeration factor and scaling factors to account for differences between vertical and horizontal units.

The value 0 is used as the output nodata value. A nodata value in the target dataset will be emitted if at least one pixel set to the nodata value is found in the 3x3 window centered around each source pixel. By default, the algorithm will compute values at image edges or if a nodata value is found in the 3x3 window, by interpolating missing values, unless `--no-edges` is specified, in which case a 1-pixel border around the image will be set with the nodata value.

In general, it assumes that x, y and z units are identical. However, if none of `--xscale` and `--yscale` are specified, and the CRS is a geographic or projected CRS, it will automatically determine the appropriate ratio from the units of the CRS, as well as the potential value of the units of the raster band (as returned by `GDALRasterBand::GetUnitType()`, if it is metre, foot international or US survey foot). Note that for geographic CRS, the result for source datasets at high latitudes may be incorrect, and prior reprojection to a polar projection might be needed using *gdal raster reproject*.

If x (east-west) and y (north-south) units are identical, but z (elevation) units are different, the `--xscale` and `--yscale`

can be used to set the ratio of vertical units to horizontal. For geographic CRS near the equator, where units of latitude and units of longitude are similar, elevation (z) units can be converted to be compatible by using scale=370400 (if elevation is in feet) or scale=111120 (if elevation is in meters). For locations not near the equator, the `--xscale` value can be taken as the `--yscale` value multiplied by the cosine of the mean latitude of the raster.

GDALG output (on-the-fly / streamed dataset)

This program supports serializing the command line as a JSON file using the `GDALG` output format. The resulting file can then be opened as a raster dataset using the *GDALG: GDAL Streamed Algorithm* driver, and apply the specified pipeline in a on-the-fly / streamed way.

Program-Specific Options

--altitude <ALTITUDE>

Altitude of the light, in degrees. 90 if the light comes from above the DEM, 0 if it is raking light. The default value is 45 degree.

This option is mutually exclusive with `--variant=Igor`.

--azimuth <AZIMUTH>

Azimuth of the light, in degrees. 0 if it comes from the top of the raster, 90 from the east, ... The default value, 315, should rarely be changed as it is the value generally used to generate shaded maps.

This option is mutually exclusive with `--variant=multidirectional`.

-b, --band <BAND>

Index (starting at 1) of the band to which the hillshade must be computed.

--gradient-alg `Horn|ZevenbergenThorne`

Algorithm used to compute terrain gradient. The default is `Horn`. The literature suggests Zevenbergen & Thorne to be more suited to smooth landscapes, whereas Horn's formula to perform better on rougher terrain.

--no-edges

Do not try to interpolate values at dataset edges or close to nodata values

--variant `regular|combined|multidirectional|Igor`

Variant of the hillshading algorithm:

- `regular`: the hillshade values combines the computed slope with the azimuth and altitude of the illumination according to:

$$Hillshade = 1 + 254.0 * ((\sin(altitude) * cos(slope)) + (cos(altitude) * sin(slope) * cos(azimuth - \frac{\pi}{2} - aspec$$

- `combined`: combined shading, a combination of slope and oblique shading.
- `multidirectional`: multidirectional shading, a combination of hillshading illuminated from 225 deg, 270 deg, 315 deg, and 360 deg azimuth. Applies the formula of http://pubs.usgs.gov/of/1992/of92-422/of92-422.pdf
- `Igor`: shading which tries to minimize effects on other map features beneath. Igor's hillshading uses formula from Maperitive: http://maperitive.net/docs/Commands/GenerateReliefImageIgor.html

--xscale <scale>

Added in version 3.11.

Ratio of vertical units to horizontal X axis units. If the horizontal unit of the source DEM is degrees (e.g Lat/Long WGS84 projection), you can use scale=111120 if the vertical units are meters (or scale=370400 if they are in feet).

If none of *--xscale* and *--yscale* are specified, and the CRS is a geographic or projected CRS, **gdal raster hillshade** will automatically determine the appropriate ratio from the units of the CRS, as well as the potential value of the units of the raster band (as returned by *GDALRasterBand::GetUnitType()*, if it is metre, foot international or US survey foot). Note that for geographic CRS, the result for source datasets at high latitudes may be incorrect, and prior reprojection to a polar projection might be needed.

If *--xscale* is specified, *--yscale* must also be specified.

--yscale <scale>

Added in version 3.11.

Ratio of vertical units to horizontal Y axis units. If the horizontal unit of the source DEM is degrees (e.g Lat/Long WGS84 projection), you can use scale=111120 if the vertical units are meters (or scale=370400 if they are in feet)

If none of *--xscale* and *--yscale* are specified, and the CRS is a geographic or projected CRS, **gdal raster hillshade** will automatically determine the appropriate ratio from the units of the CRS, as well as the potential value of the units of the raster band (as returned by *GDALRasterBand::GetUnitType()*, if it is metre, foot international or US survey foot). Note that for geographic CRS, the result for source datasets at high latitudes may be incorrect, and prior reprojection to a polar projection might be needed.

If *--yscale* is specified, *--xscale* must also be specified.

-z, --zfactor <ZFACTOR>

Vertical exaggeration used to pre-multiply the elevations

Standard Options

--append

Append input raster as a new subdataset to an existing output file. Only works with drivers that support adding subdatasets such as *GTiff -- GeoTIFF File Format* and *GPKG -- GeoPackage raster* This also creates the output dataset if it does not exist yet.

--co, --creation-option <NAME>=<VALUE>

Many formats have one or more optional creation options that can be used to control particulars about the file created. For instance, the GeoTIFF driver supports creation options to control compression, and whether the file should be tiled.

May be repeated.

The creation options available vary by format driver, and some simple formats have no creation options at all. A list of options supported for a format can be listed with the *--formats* command line option but the documentation for the format is the definitive source of information on driver creation options. See *Raster drivers* format specific documentation for legal creation options for each format.

--if, --input-format <format>

Format/driver name to be attempted to open the input file(s). It is generally not necessary to specify it, but it can be used to skip automatic driver detection, when it fails to select the appropriate driver. This option can be repeated several times to specify several candidate drivers. Note that it does not force those drivers to open the dataset. In particular, some drivers have requirements on file extensions.

May be repeated.

--oo, --open-option <NAME>=<VALUE>

Dataset open option (format specific).

May be repeated.

-f, --of, --format, --output-format <OUTPUT-FORMAT>

Which output raster format to use. Allowed values may be given by `gdal --formats | grep raster | grep rw | sort`

--overwrite

Allow program to overwrite existing target file or dataset. Otherwise, by default, **gdal** errors out if the target file or dataset already exists.

Return status code

The program returns status code 0 in case of success, and non-zero in case of error (non-blocking errors emitted as warnings are considered as a successful execution).

Examples

Example 1: Generates a shaded relief map from a DTED0 file, using a vertical exaggeration factor of 30.

```
$ gdal raster hillshade --zfactor=30 n43.dt0 out.tif --overwrite
```

Example 2: Combine the output of shaded relief map and hypsometric rendering on a DEM to create a colorized shaded relief map.

```
$ gdal pipeline read n43.tif ! \
                color-map --color-map color_file.txt ! \
                blend --operator=hsv-value --overlay \
                    [ read n43.tif ! hillshade -z 30 ] ! \
                write out.tif --overwrite
```

5.1.3.18 gdal raster index

Added in version 3.11.

Synopsis

```
Usage: gdal raster index [OPTIONS] <INPUT>... <OUTPUT>

Create a vector index of raster datasets.

Positional arguments:
  -i, --input <INPUT>                                Input raster datasets [may be␣
↪repeated] [required]
  -o, --output <OUTPUT>                              Output vector dataset [required]

Common Options:
  -h, --help                                         Display help message and exit
  --json-usage                                       Display usage as JSON document␣
↪and exit
```

(continues on next page)

(continued from previous page)

```
  --config <KEY>=<VALUE>                                  Configuration option [may be␣
↪repeated]
  -q, --quiet                                             Quiet mode (no progress bar or␣
↪warning message) [not available in pipelines]

Options:
  -f, --of, --format, --output-format <OUTPUT-FORMAT>  Output format
  --co, --creation-option <KEY>=<VALUE>                   Creation option [may be repeated]
  --lco, --layer-creation-option <KEY>=<VALUE>            Layer creation option [may be␣
↪repeated]
  --overwrite                                             Whether overwriting existing␣
↪output dataset is allowed
                                                          Mutually exclusive with --update
  --update                                                Whether to open existing dataset␣
↪in update mode
                                                          Mutually exclusive with --
↪overwrite
  --overwrite-layer                                       Whether overwriting existing␣
↪output layer is allowed
  --append                                                Whether appending to existing␣
↪layer is allowed
  --nln, --output-layer <OUTPUT-LAYER>                    Output layer name
  --recursive                                             Whether input directories should␣
↪be explored recursively.
  --filename-filter <FILENAME-FILTER>                     Pattern that the filenames in␣
↪input directories should follow ('*' and '?' wildcard) [may be repeated]
  --min-pixel-size <MIN-PIXEL-SIZE>                       Minimum pixel size in term of␣
↪geospatial extent per pixel (resolution) that a raster should have to be selected.
  --max-pixel-size <MAX-PIXEL-SIZE>                       Maximum pixel size in term of␣
↪geospatial extent per pixel (resolution) that a raster should have to be selected.
  --location-name <LOCATION-NAME>                         Name of the field with the raster␣
↪path (default: location)
  --absolute-path                                         Whether the path to the input␣
↪datasets should be stored as an absolute path
  --output-crs <OUTPUT-CRS>                               Output CRS
  --metadata <KEY>=<VALUE>                                Add dataset metadata item [may be␣
↪repeated]
  --skip-errors                                           Skip errors related to input␣
↪datasets
  --profile <PROFILE>                                     Profile of output dataset.␣
↪PROFILE=none|STAC-GeoParquet (default: none)
  --base-url <BASE-URL>                                   Base URL for STAC-GeoParquet href
  --id-method <ID-METHOD>                                 How to derive STAC-GeoParquet 'id
↪'. ID-METHOD=filename|md5|metadata-item (default: filename)
  --id-metadata-item <ID-METADATA-ITEM>                   Name of metadata item used to set␣
↪STAC-GeoParquet 'id' (default: id)
  --source-crs-field-name <SOURCE-CRS-FIELD-NAME>         Name of the field to store the␣
↪CRS of each dataset
  --source-crs-format <SOURCE-CRS-FORMAT>                 Format in which the CRS of each␣
↪dataset must be written. SOURCE-CRS-FORMAT=auto|WKT|EPSG|PROJ (default: auto)
```

Description

gdal raster index creates a vector dataset with a record for each input raster file, an attribute containing the filename, and a polygon geometry outlining the raster. This output is suitable for use with MapServer as a raster tileindex

See *gdal driver gti create* for an extension of this command that create files to be used as input for the *GTI* driver.

The following options are available:

Program-Specific Options

--absolute-path

The absolute path to the raster files is stored in the index file. By default the raster filenames will be put in the file exactly as they are specified on the command line.

--base-url <BASE-URL>

Added in version 3.13.

Base URL for STAC-GeoParquet the `href` property of the *id* property in a STAC-GeoParquet index.

--filename-filter <FILENAME-FILTER>

Pattern that the filenames contained in input directories should follow. '*' is a wildcard character that matches any number of any characters including none. '?' is a wildcard character that matches a single character. Comparisons are done in a case insensitive way. Several filters may be specified.

For example: `--filename-filter "*.tif,*.tiff"`

--id-metadata-item <ID-METADATA-ITEM>

Added in version 3.13.

Name of metadata item used to set STAC-GeoParquet *id* property. Defaults to `id`.

--id-method `filename|md5|metadata-item`

Added in version 3.13.

How to derive STAC-GeoParquet *id* property

- `filename` (the default): only the filename (without directory, but including extension) is used
- `md5`: the MD5Sum of the file is computed, and suffixed with the filename.
- `metadata-item`: the value of the metadata item defined by *--id-metadata-item* from each source dataset is used.

--location-name <LOCATION-NAME>

The output field name to hold the file path/location to the indexed rasters. The default field name is `location`.

--max-pixel-size <val>

Maximum pixel size in term of geospatial extent per pixel (resolution) that a raster should have to be selected. The pixel size is evaluated after reprojection of its extent to the target CRS defined by *--output-crs*.

--metadata <KEY>=<VALUE>

Write an arbitrary layer metadata item, for formats that support layer metadata. This option may be repeated.

--min-pixel-size <val>

Minimum pixel size in term of geospatial extent per pixel (resolution) that a raster should have to be selected. The pixel size is evaluated after reprojection of its extent to the target CRS defined by *--output-crs*.

--output-crs <OUTPUT-CRS>

Geometries of input files will be transformed to the desired target coordinate reference system. Default creates simple rectangular polygons in the same coordinate reference system as the input rasters.

--profile none|STAC-GeoParquet

Added in version 3.13.

Defines the profile of the output dataset. If selecting STAC-GeoParquet, a Parquet file conforming to the STAC-GeoParquet specification is created (provided that the Parquet format is also selected). Such file can be read by the *GTI driver*. Setting STAC-GeoParquet also implicitly sets the target CRS to EPSG:4326.

--recursive

Whether input directories should be explored recursively.

--skip-errors

Added in version 3.12.

Skip errors related to input datasets.

--source-crs-field-name <SOURCE-CRS-FIELD-NAME>

The name of the field to store the CRS of each tile. This field name can be used as the value of the TILESRS keyword in MapServer

--source-crs-format auto|WKT|EPSG|PROJ

The format in which the CRS of each tile must be written. Types can be auto, WKT, EPSG, PROJ. This option should be used together with *--source-crs-field-name*.

Standard Options

--append

Whether appending features to existing layer(s) is allowed. This also creates the output dataset if it does not exist yet.

--co, --creation-option <NAME>=<VALUE>

Many formats have one or more optional creation options that can be used to control particulars about the file created. For instance, the GeoTIFF driver supports creation options to control compression, and whether the file should be tiled.

May be repeated.

The creation options available vary by format driver, and some simple formats have no creation options at all. A list of options supported for a format can be listed with the *--formats* command line option but the documentation for the format is the definitive source of information on driver creation options. See *Raster drivers* format specific documentation for legal creation options for each format.

--lco, --layer-creation-option <NAME>=<VALUE>

Many formats have one or more optional layer creation options that can be used to control particulars about the layer created. For instance, the GeoPackage driver supports layer creation options to control the feature identifier or geometry column name, setting the identifier or description, etc.

May be repeated.

The layer creation options available vary by format driver, and some simple formats have no layer creation options at all. A list of options supported for a format can be listed with the *--formats* command line option but the documentation for the format is the definitive source of information on driver creation options. See *Vector drivers* format specific documentation for legal creation options for each format.

Note that layer creation options are different from dataset creation options.

-f, --of, --format, --output-format <OUTPUT-FORMAT>

Which output vector format to use. Allowed values may be given by `gdal --formats | grep vector | grep rw | sort`

--nln, --output-layer <LAYER>

Provides a name for the output vector layer.

--overwrite

Allow program to overwrite existing target file or dataset. Otherwise, by default, **gdal** errors out if the target file or dataset already exists.

--overwrite-layer

Whether overwriting the existing output vector layer is allowed.

--update

Whether the output dataset must be opened in update mode. Implies that it already exists.

Return status code

The program returns status code 0 in case of success, and non-zero in case of error (non-blocking errors emitted as warnings are considered as a successful execution).

Examples

Example 1

Produce a GeoPackage with a record for every image that the utility found in the `doq` folder. Each record holds information that points to the location of the image and also a bounding rectangle shape showing the bounds of the image:

```
gdal raster index doq/*.tif doq_index.gpkg
```

Example 2

The *--output-crs* option can also be used to transform all input raster geometries into the same output projection:

```
gdal raster index --output-crs EPSG:4326 --source-crs-field-name=src_srs *.tif tile_
↪index_mixed_crs.gpkg
```

Example 3: Creates a STAC-GeoParquet compliant index.

```
gdal raster index --profile STAC-GeoParquet  *.tif index.parquet
```

5.1.3.19 gdal raster materialize

Added in version 3.12.

Description

The `materialize` operation is for use only in a pipeline, and writes the incoming dataset to a dataset on disk, before passing that materialized dataset to following steps. This can be used when materializing a dataset helps for performance compared to on-demand evaluation of previous steps.

By default, a tiled compressed GeoTIFF file is used for the materialized dataset, created in the directory pointed by the *CPL_TMPDIR* configuration option or in the current directory if not specified, and is deleted when the pipeline finishes. The user can also select another format, or specify an explicit filename, in which case the materialized dataset is not deleted when the pipeline finishes.

> **Note**
>
> VRT output is not compatible with materialize

Synopsis

```
* materialize [OPTIONS]
-----------------------

Materialize a piped dataset on disk to increase the efficiency of the following steps.

Options:
  -o, --output <OUTPUT>                                Materialized dataset name␣
↪(created by algorithm)
  -f, --of, --format, --output-format <OUTPUT-FORMAT>  Output format
  --co, --creation-option <KEY>=<VALUE>                Creation option [may be repeated]
  --overwrite                                          Whether overwriting existing␣
↪output dataset is allowed
```

Program-Specific Options

--output <OUTPUT>

Optional dataset name. When specified, it is not removed at the end of the process.

Standard Options

--co, --creation-option <NAME>=<VALUE>

Many formats have one or more optional creation options that can be used to control particulars about the file created. For instance, the GeoTIFF driver supports creation options to control compression, and whether the file should be tiled.

May be repeated.

The creation options available vary by format driver, and some simple formats have no creation options at all. A list of options supported for a format can be listed with the *--formats* command line option but the documentation for the format is the definitive source of information on driver creation options. See *Raster drivers* format specific documentation for legal creation options for each format.

-f, --of, --format, --output-format <OUTPUT-FORMAT>

Which output raster format to use. Allowed values may be given by `gdal --formats | grep raster | grep rw | sort`

--overwrite

Allow program to overwrite existing target file or dataset. Otherwise, by default, **gdal** errors out if the target file or dataset already exists.

Return status code

The program returns status code 0 in case of success, and non-zero in case of error (non-blocking errors emitted as warnings are considered as a successful execution).

Examples

Example 1: Reproject a GeoTIFF file to CRS EPSG:32632 ("WGS 84 / UTM zone 32N"), materialize it to a temporary file and compute its contour lines

```
$ gdal pipeline ! read in.tif ! reproject --output-crs=EPSG:32632 ! \
                ! materialize ! contour --interval=10 ! write out.gpkg --overwrite
```

Example 2: How to use materialize for Cloud Optimized GeoTIFF (COG)

Usually when you want load COG data, you are not loading the whole data but instead on certain region and using lower resolution for fast analysis. Therefore, after using command *read*, it is not supposed to be materialize right away because it mean it will download the whole thing into the memory/disk. Instead, you could use command *reproject* and use *--bbox* to limit the region of interest and set *--size* or *--resolution* to use lower resolution overview.

```
$ gdal pipeline ! read /vsicurl/https://some.storage.com/mydata/landcover.tif \
                ! reproject -r mode -d EPSG:4326 --bbox=112,2,116,4.5 --bbox-
↪crs=EPSG:4326 --size=3000,3000 \
                ! materialize \
                ! zonal-stats --zones=/vsicurl/https://some.storage.com/mydata/adm_
↪level4.fgb --stat=values \
                ! write out.geojson
```

5.1.3.20 gdal raster mosaic

Added in version 3.11.

Synopsis

```
Usage: gdal raster mosaic [OPTIONS] <INPUTS>... <OUTPUT>

Build a mosaic, either virtual (VRT) or materialized.

Positional arguments:
  -i, --input <INPUTS>                                          Input raster datasets␣
↪(or specify a @<filename> to point to a file containing filenames) [1.. values]␣
↪[required] [not available in pipelines]
  -o, --output <OUTPUT>                                         Output raster dataset␣
↪[required] [not available in pipelines]

Common Options:
  -h, --help                                                    Display help message␣
↪and exit
  --json-usage                                                  Display usage as JSON␣
↪document and exit
  --config <KEY>=<VALUE>                                        Configuration option␣
↪[may be repeated]
  -q, --quiet                                                   Quiet mode (no␣
↪progress bar or warning message) [not available in pipelines]

Options:
  -f, --of, --format, --output-format <OUTPUT-FORMAT>           Output format ("GDALG"␣
```

(continues on next page)

(continued from previous page)

```
↪allowed) [not available in pipelines]
  --co, --creation-option <KEY>=<VALUE>                          Creation option [may␣
↪be repeated] [not available in pipelines]
  --overwrite                                                    Whether overwriting␣
↪existing output dataset is allowed [not available in pipelines]
                                                                 Mutually exclusive␣
↪with --append
  --append                                                       Append as a subdataset␣
↪to existing output [not available in pipelines]
                                                                 Mutually exclusive␣
↪with --overwrite
  -b, --band <BAND>                                              Input band(s) (1-based␣
↪index) [may be repeated]
  --absolute-path                                                Whether the path to␣
↪the input datasets should be stored as an absolute path
  --resolution <xres>,<yres>|same|average|common|highest|lowest>  Target resolution (in␣
↪destination CRS units) (default: same)

↪repeated] [not available in pipelines]
```

Description

This program builds a mosaic of a list of input GDAL datasets, that can be either a virtual mosaic in the *VRT (Virtual Dataset)* format, or in a more conventional raster format such as GeoTIFF.

Wildcards '*', '?' or '[']' of *VSIGlob()* can be used for input dataset names, even on files located on network file systems such as /vsis3/, /vsigs/, /vsiaz/, etc. Alternatively if a input dataset name is prefixed by the @ character, it will be assumed to contain the list of actual dataset names (one per line) to use as input datasets.

gdal raster mosaic does some checks to ensure that all files that will be put in the resulting file have similar characteristics: number of bands, projection, color interpretation, etc. If not, files that do not match the common characteristics will be skipped.

Starting with GDAL 3.12, a function (e.g., `min`, `mean`, `median`) can be specified (*--pixel-function*) to calculate pixel values from overlapping inputs. If no function is specified, or in earlier versions, the order of the input list is used to determine priority. Files that are listed at the end are the ones from which the content will be fetched. Note that nodata will be taken into account to potentially fetch data from lower-priority datasets, but currently, alpha channel is not taken into account to do alpha compositing (so a source with alpha=0 appearing on top of another source will override its content). This might be changed in later versions.

Stating with GDAL 3.12, this command can also be used as the first step of *gdal raster pipeline*.

GDALG output (on-the-fly / streamed dataset)

This program supports serializing the command line as a JSON file using the `GDALG` output format. The resulting file can then be opened as a raster dataset using the *GDALG: GDAL Streamed Algorithm* driver, and apply the specified pipeline in a on-the-fly / streamed way.

Program-Specific Options

--absolute-path

Added in version 3.12.0.

When writing a VRT file, enables writing the absolute path of the input datasets. By default, input filenames are written in a relative way with respect to the VRT filename (when possible).

--add-alpha

Adds an alpha mask band to the output when the source raster have none. Mainly useful for RGB sources (or grey-level sources). The alpha band is filled on-the-fly with the value 0 in areas without any source raster, and with value 255 in areas with source raster. The effect is that a RGBA viewer will render the areas without source rasters as transparent and areas with source rasters as opaque.

-b, --band <band>

Select an input <band> to be processed. Bands are numbered from 1. If input bands not set all bands will be added to the output. Multiple *-b* switches may be used to select a set of input bands.

--bbox <xmin>,<ymin>,<xmax>,<ymax>

Set georeferenced extents of output file. The values must be expressed in georeferenced units. If not specified, the extent of the output is the minimum bounding box of the set of source rasters. Pixels within the extent of the output but not covered by a source raster will be read as valid pixels with a value of zero unless a NODATA value is specified using *--output-nodata* or an alpha mask band is added with *--add-alpha*.

--hide-nodata

Even if any band contains nodata value, giving this option makes the output band not report the NoData. Useful when you want to control the background color of the dataset. By using along with the *--add-alpha* option, you can prepare a dataset which doesn't report nodata value but is transparent in areas with no data.

--input-nodata <value>[,<value>]...

Set nodata values for input bands (different values can be supplied for each band). If the option is not specified, the intrinsic nodata settings on the source datasets will be used (if they exist). The value set by this option is written in the NODATA element of each `ComplexSource` element.

--output-nodata <value>[,<value>]...

Set nodata values at the output band level (different values can be supplied for each band). If more than one value is supplied, all values should be quoted to keep them together as a single operating system argument (*Example 1*). If the option is not specified, intrinsic nodata settings on the first dataset will be used (if they exist). The

value set by this option is written in the `NoDataValue` element of each `VRTRasterBand element`. Use a value of *None* to ignore intrinsic nodata settings on the source datasets.

--pixel-function

Specify a function name to calculate a value from overlapping inputs. For a list of available pixel functions, see *Built-in Pixel Functions*. If no function is specified, values will be taken from the last overlapping input.

Added in version 3.12.

--pixel-function-arg

Specify an argument to be provided to a pixel function, in the format `<NAME>=<VALUE>`. Multiple arguments may be specified by repeating this option.

Added in version 3.12.

--resolution `{<xres,yres>|same|highest|lowest|average}`

In case the resolution of all input files is not the same, the `--resolution` flag enables the user to control the way the output resolution is computed.

same, the default, checks that all source rasters have the same resolution and errors out when this is not the case.

highest will pick the smallest values of pixel dimensions within the set of source rasters.

lowest will pick the largest values of pixel dimensions within the set of source rasters.

average will compute an average of pixel dimensions within the set of source rasters.

common determines the greatest common divisor of the source pixel dimensions, e.g. 0.2 for source pixel dimensions of 0.4 and 0.6.

<xres>,<yres>. The values must be expressed in georeferenced units. Both must be positive values.

--target-aligned-pixels

(target aligned pixels) align the coordinates of the extent of the output file to the values of the `--resolution`, such that the aligned extent includes the minimum extent. Alignment means that xmin / resx, ymin / resy, xmax / resx and ymax / resy are integer values.

Standard Options

--append

Append input raster as a new subdataset to an existing output file. Only works with drivers that support adding subdatasets such as *GTiff -- GeoTIFF File Format* and *GPKG -- GeoPackage raster* This also creates the output dataset if it does not exist yet.

--co, --creation-option `<NAME>=<VALUE>`

Many formats have one or more optional creation options that can be used to control particulars about the file created. For instance, the GeoTIFF driver supports creation options to control compression, and whether the file should be tiled.

May be repeated.

The creation options available vary by format driver, and some simple formats have no creation options at all. A list of options supported for a format can be listed with the *--formats* command line option but the documentation for the format is the definitive source of information on driver creation options. See *Raster drivers* format specific documentation for legal creation options for each format.

--if, --input-format `<format>`

Format/driver name to be attempted to open the input file(s). It is generally not necessary to specify it, but it can be used to skip automatic driver detection, when it fails to select the appropriate driver. This option can be

repeated several times to specify several candidate drivers. Note that it does not force those drivers to open the dataset. In particular, some drivers have requirements on file extensions.

May be repeated.

--oo, --open-option <NAME>=<VALUE>

Dataset open option (format specific).

May be repeated.

-f, --of, --format, --output-format <OUTPUT-FORMAT>

Which output raster format to use. Allowed values may be given by `gdal --formats | grep raster | grep rw | sort`

--overwrite

Allow program to overwrite existing target file or dataset. Otherwise, by default, **gdal** errors out if the target file or dataset already exists.

Return status code

The program returns status code 0 in case of success, and non-zero in case of error (non-blocking errors emitted as warnings are considered as a successful execution).

Examples

Example 1: Make a virtual mosaic with blue background colour (RGB: 0 0 255)

```
gdal raster mosaic --hide-nodata --output-nodata=0,0,255 doq/*.tif doq_index.vrt
```

Example 2: Create a Cloud Optimized GeoTIFF (COG) mosaic from all GeoTIFFs in a folder

Because the size of the resulting GeoTIFF will be more than 4 GB, the *BIGTIFF=YES* creation option is used.

```
gdal raster mosaic --output-format COG --creation-option BIGTIFF=YES *.tif mosaic.tif
```

5.1.3.21 gdal raster neighbors

Added in version 3.12.

Synopsis

```
Usage: gdal raster neighbors [OPTIONS] <INPUT> <OUTPUT>

Compute the value of each pixel from its neighbors (focal statistics)

```

Description

gdal raster neighbors applies a kernel (convolution matrix) and a method to compute the target pixel value from a neighbourhood of the source pixel value.

At the top edge, the values of the first row are replicated to virtually extend the source window by a number of rows equal to the radius of the kernel. And similarly for the bottom, left and right edges. This strategy may potentially lead to unexpected results depending on the applied kernel.

For a given target cell, if the corresponding source value (the one at the center of the kernel) is nodata, the resulting pixel is nodata. For other source values in the neighborhood defined by the kernel, source nodata values are ignored.

This algorithm can be part of a *gdal pipeline* or *gdal raster pipeline*.

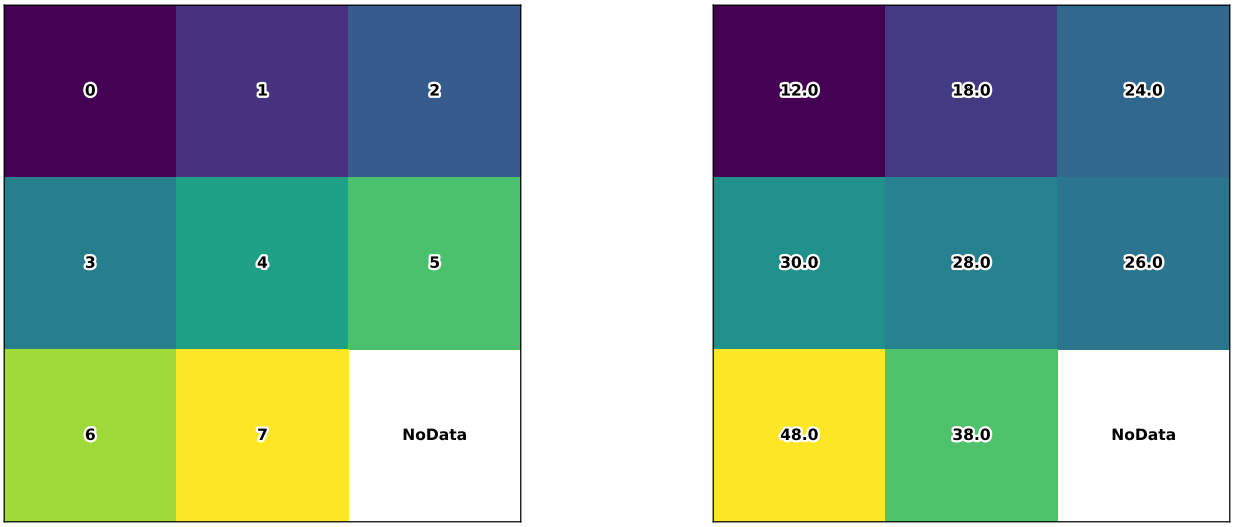

Fig. 1: Raster dataset before (left) and after (right) summation with a 3x3 equal-weight kernel. NoData values are considered zero for the purpose of the summation. Edge cells are replicated where the kernel window extends beyond the edge of the dataset.

GDALG output (on-the-fly / streamed dataset)

This program supports serializing the command line as a JSON file using the `GDALG` output format. The resulting file can then be opened as a raster dataset using the *GDALG: GDAL Streamed Algorithm* driver, and apply the specified pipeline in a on-the-fly / streamed way.

Program-Specific Options

`--band` `<BAND>`

Source band number (indexing starts at one). If it is not specified, all input bands are used.

`--kernel`

Convolution kernel to apply to source pixels in a neighborhood of each pixel.

- either the name of a well-known kernel, among `edge1`, `edge2`, `sharpen`, `gaussian`, or `unsharp-masking`, corresponding to those kernels (convolution matrix), with the addition of:
  - `equal` corresponding to a kernel with all coefficients at one kernel size can be any odd number between 3 and 99):

$$\begin{bmatrix} 1 & 1 & 1 \\ 1 & 1 & 1 \\ 1 & 1 & 1 \end{bmatrix} \tag{5.1}$$

    For method `mean`, this corresponds to a box blur filter.
  - `u` corresponding to an horizontal derivative with coefficients:

$$\begin{bmatrix} 0 & 0 & 0 \\ -0.5 & 0 & 0.5 \\ 0 & 0 & 0 \end{bmatrix} \tag{5.2}$$

- v corresponding to a vertical derivative with coefficients:

$$\begin{bmatrix} 0 & -0.5 & 0 \\ 0 & 0 & 0 \\ 0 & 0.5 & 0 \end{bmatrix} \tag{5.3}$$

edge1, edge2, sharpen, u and v are only supported for a kernel size equal to 3.

gaussian is supported for a kernel size equal to 3 or 5.

unsharp-masking is supported for a kernel size equal to 5.

- or the values of the coefficients of the kernel as a square matrix of width and height N, where N is an odd number, as `[[val00, val01, ..., val0N],[val10, val11, ..., val1N],...,[valN0, valN1, ..., valNN]]`.

  If *--method* is set to mean, this has the effect of adding the sum of the (contributing, i.e. non nodata) weighted source pixels and dividing it by the sum of the coefficients in the kernel.

If *--kernel* is specified several times, there will one output band for each combination of kernel and input band.

--method sum|mean|min|max|stddev|median|mode

Function to apply to the weighted source pixels in the neighborhood defined by the kernel. Defaults to mean, except when *--kernel* is set to u, v, edge1, edge2, or a user defined kernel whose sum of coefficients is zero, in which case sum is used.

- sum: computes the sum of the value of contributing source pixels multiplied by the corresponding weight of the kernel. This corresponds to a kernel with un-normalized sum of coefficients.
- mean: computes the average of the value of contributing source pixels multiplied by the corresponding weight of the kernel. This has the effect of normalizing kernel coefficients so their sum is one.
- min: computes the minimum of the value of contributing source pixels multiplied by the corresponding weight of the kernel
- max: computes the maximum of the value of contributing source pixels multiplied by the corresponding weight of the kernel
- stddev: computes the standard deviation of the value of contributing source pixels multiplied by the corresponding weight of the kernel
- median: computes the median of the value of contributing source pixels multiplied by the corresponding weight of the kernel
- mode (majority): computes the most frequent of the value of contributing source pixels multiplied by the corresponding weight of the kernel

--nodata

Set the NoData value for the output dataset. May be set to none to leave the NoData value undefined. If *--nodata* is not specified, **gdal raster neighbors** will use a NoData value from the first source dataset to have one.

--size <SIZE>

Size of the kernel. Odd number between 3 and 99.

> **Note**
>
> Computation time is proportional to the square of the kernel size.

For kernels edge1, edge2, sharpen, u, v, gaussian, equal, defaults to 3.

For kernel `unsharp-masking`, defaults to 5.

For kernels specified through their coefficient values, it is deduced from the shape of the matrix.

Standard Options

--append

Append input raster as a new subdataset to an existing output file. Only works with drivers that support adding subdatasets such as *GTiff -- GeoTIFF File Format* and *GPKG -- GeoPackage raster* This also creates the output dataset if it does not exist yet.

--co, --creation-option <NAME>=<VALUE>

Many formats have one or more optional creation options that can be used to control particulars about the file created. For instance, the GeoTIFF driver supports creation options to control compression, and whether the file should be tiled.

May be repeated.

The creation options available vary by format driver, and some simple formats have no creation options at all. A list of options supported for a format can be listed with the *--formats* command line option but the documentation for the format is the definitive source of information on driver creation options. See *Raster drivers* format specific documentation for legal creation options for each format.

--if, --input-format <format>

Format/driver name to be attempted to open the input file(s). It is generally not necessary to specify it, but it can be used to skip automatic driver detection, when it fails to select the appropriate driver. This option can be repeated several times to specify several candidate drivers. Note that it does not force those drivers to open the dataset. In particular, some drivers have requirements on file extensions.

May be repeated.

--oo, --open-option <NAME>=<VALUE>

Dataset open option (format specific).

May be repeated.

-f, --of, --format, --output-format <OUTPUT-FORMAT>

Which output raster format to use. Allowed values may be given by `gdal --formats | grep raster | grep rw | sort`

--ot, --datatype, --output-data-type <OUTPUT-DATA-TYPE>

Output data type among `Byte`, `Int8`, `UInt16`, `Int16`, `UInt32`, `Int32`, `UInt64`, `Int64`, `CInt16`, `CInt32`, `Float32`, `Float64`, `CFloat32`, `CFloat64`.

--overwrite

Allow program to overwrite existing target file or dataset. Otherwise, by default, **gdal** errors out if the target file or dataset already exists.

Return status code

The program returns status code 0 in case of success, and non-zero in case of error (non-blocking errors emitted as warnings are considered as a successful execution).

Examples

Example 1: Compute the horizontal and vertical derivative of a single-band raster

```
gdal raster neighbors --kernel u --kernel v in.tif uv.tif
```

Example 2: Compute the average value around each pixel in a 3x3 neighborhood

```
gdal raster neighbors --kernel equal --method mean in.tif mean.tif
```

Example 3: Compute the maximum value around each pixel in a 5x5 neighborhood

```
gdal raster neighbors --kernel equal --size 5 --method max in.tif max.tif
```

Example 4: Compute a sharpen filter of a single-band raster, by manually specifying the kernel coefficients.

```
gdal raster neighbors "--kernel=[[0,-1,0],[-1,5,-1],[0,-1,0]]" in.tif sharpen.tif
```

5.1.3.22 gdal raster nodata-to-alpha

Added in version 3.12.

Synopsis

```
Usage: gdal raster nodata-to-alpha [OPTIONS] <INPUT> <OUTPUT>

Replace nodata value(s) with an alpha band.

Positional arguments:
  -i, --input <INPUT>                                    Input raster datasets [required]␣

↪[not available in pipelines]
```

Description

gdal raster nodata-to-alpha adds an alpha band based on the nodata value metadata set on the bands of the input dataset.

If there is no explicit nodata value on the input dataset, it is possible to add it with the *--nodata* option.

This program is a no-op and can be safely used if the input dataset has no nodata value and *--nodata* is not specified.

GDALG output (on-the-fly / streamed dataset)

This program supports serializing the command line as a JSON file using the GDALG output format. The resulting file can then be opened as a raster dataset using the *GDALG: GDAL Streamed Algorithm* driver, and apply the specified pipeline in a on-the-fly / streamed way.

Program-Specific Options

--nodata <NODATA>

Override nodata value of input band(s) (numeric value, 'nan', 'inf', '-inf'). Either one value can be specified or as many values as they are input bands. When multiple values are specified, a pixel is considered as invalid only if it matches the nodata values on all bands.

Standard Options

--co, --creation-option <NAME>=<VALUE>

Many formats have one or more optional creation options that can be used to control particulars about the file created. For instance, the GeoTIFF driver supports creation options to control compression, and whether the file should be tiled.

May be repeated.

The creation options available vary by format driver, and some simple formats have no creation options at all. A list of options supported for a format can be listed with the *--formats* command line option but the documentation for the format is the definitive source of information on driver creation options. See *Raster drivers* format specific documentation for legal creation options for each format.

-f, --of, --format, --output-format <OUTPUT-FORMAT>

Which output raster format to use. Allowed values may be given by `gdal --formats | grep raster | grep rw | sort`

--ot, --datatype, --output-data-type <OUTPUT-DATA-TYPE>

Output data type among Byte, Int8, UInt16, Int16, UInt32, Int32, UInt64, Int64, CInt16, CInt32, Float32, Float64, CFloat32, CFloat64.

Return status code

The program returns status code 0 in case of success, and non-zero in case of error (non-blocking errors emitted as warnings are considered as a successful execution).

Examples

Example 1

```
$ gdal raster nodata-to-alpha input_with_nodata.tif output_with_alpha_band.tif
```

5.1.3.23 gdal raster overview

Added in version 3.11.

Synopsis

```
Usage: gdal raster overview <SUBCOMMAND> [OPTIONS]
where <SUBCOMMAND> is one of:
  - add:     Adding overviews.
  - delete:  Deleting overviews.
  - refresh: Refresh overviews.

Common Options:
  -h, --help              Display help message and exit
  --json-usage            Display usage as JSON document and exit
  --config <KEY>=<VALUE>  Configuration option [may be repeated]
```

Return status code

The program returns status code 0 in case of success, and non-zero in case of error (non-blocking errors emitted as warnings are considered as a successful execution).

Available sub-commands

- *gdal raster overview add*
- *gdal raster overview delete*
- *gdal raster overview refresh*

5.1.3.24 gdal raster overview add

Added in version 3.11.

Synopsis

```
Usage: gdal raster overview add [OPTIONS] <INPUT>

Adding overviews.

Positional arguments:
  -i, --dataset, --input <INPUT>         Dataset (to be updated in-place, unless --
↪external) [required]

Common Options:
  -h, --help                             Display help message and exit
  --json-usage                           Display usage as JSON document and exit
  --config <KEY>=<VALUE>                 Configuration option [may be repeated]
  -q, --quiet                            Quiet mode (no progress bar or warning message)␣
↪[not available in pipelines]

Options:
  --overview-src <OVERVIEW-SRC>          Source overview dataset [may be repeated]
                                         Mutually exclusive with --levels
  --external                             Add external overviews
  -r, --resampling <RESAMPLING>          Resampling method.␣
↪RESAMPLING=nearest|average|cubic|cubicspline|lanczos|bilinear|gauss|average_
↪magphase|rms|mode
  --levels <LEVELS>                      Levels / decimation factors [may be repeated]
                                         Mutually exclusive with --overview-src
  --min-size <MIN-SIZE>                  Maximum width or height of the smallest␣
↪overview level.
  --co, --creation-option <KEY>=<VALUE>  Overview creation option [may be repeated]

Advanced Options:
  --oo, --open-option <KEY>=<VALUE>      Open options [may be repeated]
```

Description

gdal raster overview add can be used to build or rebuild overview images for most supported file formats with one of several downsampling algorithms.

Starting with GDAL 3.12, **gdal raster overview add** can be used as a step of a pipeline. In that case virtual overviews are generated at the output of the step, and can potentially be materialized in the final write step, when writing a GeoTIFF file with the COPY_SRC_OVERVIEWS creation option, or when writing to a COG (Cloud Optimized GeoTIFF) file.

Program-Specific Options

--co <NAME>=<VALUE>

Added in version 3.12.

Overview creation options. May be repeated.

Many formats have one or more optional creation options that can be used to control particulars about the created overviews. Options available can be obtained by looking at the `OverviewCreationOptionList` returned by `gdal --format <FORMAT-NAME>`.

Most formats will support external overviews in a GeoTIFF file in a side-car file of extension `.ovr`. You can consult the *overview creation options for GeoTIFF*.

--dataset <DATASET>

Dataset name, to be updated in-place by default (unless *--external* is specified). Required for standalone execution, implicit when run as a pipeline step

--external

Create external `.ovr` overviews as GeoTIFF files. Not available when run as a pipeline step.

--levels <level1,level2,...>

A list of overview levels to build. Each overview level must be an integer value greater or equal to 2.

When explicit levels are not specified,

- If there are already existing overviews, the corresponding levels will be used to refresh them if no explicit levels are specified.
- Otherwise, appropriate overview power-of-two factors will be selected until the smallest overview is smaller than the value of the *--min-size* switch.

Mutually exclusive with *--overview-src*

--min-size <val>

Maximum width or height of the smallest overview level. Only taken into account if explicit levels are not specified. Defaults to 256.

--overview-src <INPUT>

Added in version 3.12.

Add specified input raster datasets as overviews of the target dataset. Source overviews may come from any GDAL supported format, provided they have the same number of bands and geospatial extent than the target dataset.

That mode is currently only implemented when the target dataset is in GeoTIFF format, or when using *--external*.

Mutually exclusive with *--levels*

-r,
--resampling {nearest|average|cubic|cubicspline|lanczos|bilinear|gauss|average_magphase|rms|mode}

Select a resampling algorithm. The default is `nearest`, which is generally not appropriate if sub-pixel accuracy is desired.

When refreshing existing TIFF overviews, the previously used method, as noted in the RESAMPLING metadata item of the overview, will be used if *-r* is not specified.

The available methods are:

`nearest` applies a nearest neighbour (simple sampling) resampler.

`average` computes the average of all non-NODATA contributing pixels. This is a weighted average taking into account properly the weight of source pixels not contributing fully to the target pixel.

`bilinear` applies a bilinear convolution kernel.

`cubic` applies a cubic convolution kernel.

`cubicspline` applies a B-Spline convolution kernel.

`lanczos` applies a Lanczos windowed sinc convolution kernel.

`gauss` applies a Gaussian kernel before computing the overview, which can lead to better results than simple averaging in e.g case of sharp edges with high contrast or noisy patterns. The advised level values should be 2, 4, 8, ... so that a 3x3 resampling Gaussian kernel is selected.

`average_magphase` averages complex data in mag/phase space.

`rms` computes the root mean squared / quadratic mean of all non-NODATA contributing pixels

`mode` selects the value which appears most often of all the sampled points.

Standard Options

--co, --creation-option <NAME>=<VALUE>

Many formats have one or more optional creation options that can be used to control particulars about the file created. For instance, the GeoTIFF driver supports creation options to control compression, and whether the file should be tiled.

May be repeated.

The creation options available vary by format driver, and some simple formats have no creation options at all. A list of options supported for a format can be listed with the *--formats* command line option but the documentation for the format is the definitive source of information on driver creation options. See *Raster drivers* format specific documentation for legal creation options for each format.

--oo, --open-option <NAME>=<VALUE>

Dataset open option (format specific).

May be repeated.

Return status code

The program returns status code 0 in case of success, and non-zero in case of error (non-blocking errors emitted as warnings are considered as a successful execution).

Examples

Example 1: Create overviews, embedded in the supplied TIFF file, with automatic computation of levels

```
gdal raster overview add -r average abc.tif
```

Example 2: Create overviews, embedded in the supplied TIFF file

```
gdal raster overview add -r average --levels=2,4,8,16 abc.tif
```

Example 3: Create an external compressed GeoTIFF overview file from the ERDAS .IMG file

```
gdal raster overview add --external --levels=2,4,8,16 --co COMPRESS=YES erdas.img
```

Example 4: Create an external JPEG-compressed GeoTIFF overview file from a 3-band RGB dataset

If the dataset is a writable GeoTIFF, you also need to add the `--external` option to force the generation of external overview.

```
gdal raster overview add --co OVERVIEW=JPEG --co PHOTOMETRIC=YCBCR \
                         --co INTERLEAVE=PIXEL rgb_dataset.ext 2 4 8 16
```

Example 5: Create overviews for a specific subdataset

For example, one of potentially many raster layers in a GeoPackage (the "filename" parameter must be driver prefix, filename and subdataset name, like e.g. shown by gdalinfo):

```
gdal raster overview add GPKG:file.gpkg:layer
```

Example 6: Add 3 existing datasets at scale 1:25K, 1:50K and 1:100K as overviews of my.tif.

```
gdal raster overview add --overview-src ovr_25k.tif --overview-src ovr_50k.tif --
↪overview-src ovr_100k.tif --dataset my.tif
```

Example 7: Create a COG file with non power-of-two overview levels.

```
gdal pipeline read input.tif ! reproject --output-crs=EPSG:4326 ! add overview --levels␣
↪16,64,128 ! write output.tif --format=COG
```

5.1.3.25 gdal raster overview delete

Added in version 3.11.

Synopsis

```
Usage: gdal raster overview delete [OPTIONS] <INPUT>

Deleting overviews.

Positional arguments:
  -i, --dataset, --input <INPUT>     Dataset (to be updated in-place, unless --external)␣
↪[required]

Common Options:
  -h, --help                         Display help message and exit
  --json-usage                       Display usage as JSON document and exit
  --config <KEY>=<VALUE>             Configuration option [may be repeated]
  -q, --quiet                        Quiet mode (no progress bar or warning message)␣
↪[not available in pipelines]

Options:
  --external                         Delete external overviews

Advanced Options:
  --oo, --open-option <KEY>=<VALUE>  Open options [may be repeated]
```

Description

gdal raster overview delete can be used to delete all existing overviews of a dataset.

> **Note**

For most file formats (including GeoTIFF or GeoPackage), the space previously occupied by the removed overviews may not be reclaimed. It might be needed for use *gdal raster convert* to create a new compact dataset.

Program-Specific Options

--dataset <DATASET>

Dataset name, to be updated in-place by default (unless `--external` is specified). Required.

--external

Remove external `.ovr` overviews.

Standard Options

--oo, --open-option <NAME>=<VALUE>

Dataset open option (format specific).

May be repeated.

Return status code

The program returns status code 0 in case of success, and non-zero in case of error (non-blocking errors emitted as warnings are considered as a successful execution).

Examples

Example 1: Delete overviews of a GeoTIFF file.

```
gdal raster overview delete my.tif
```

5.1.3.26 gdal raster overview refresh

Added in version 3.12.

Synopsis

```
Usage: gdal raster overview refresh [OPTIONS] <INPUT>

Refresh overviews.

Positional arguments:
  -i, --dataset, --input <INPUT>     Dataset (to be updated in-place, unless --external)␣
↪[required]

Common Options:
  -h, --help                         Display help message and exit
  --json-usage                       Display usage as JSON document and exit
  --config <KEY>=<VALUE>             Configuration option [may be repeated]
  -q, --quiet                        Quiet mode (no progress bar or warning message)␣
↪[not available in pipelines]

Options:
  --external                         Refresh external overviews
```

(continues on next page)

(continued from previous page)

```
  -r, --resampling <RESAMPLING>      Resampling method.␣
↪RESAMPLING=nearest|average|cubic|cubicspline|lanczos|bilinear|gauss|average_
↪magphase|rms|mode
  --levels <LEVELS>                  Levels / decimation factors [may be repeated]
  --bbox <BBOX>                      Bounding box to refresh
                                     Mutually exclusive with --like, --use-source-
↪timestamp
  --like <LIKE>                      Use extent of dataset(s) [may be repeated]
                                     Mutually exclusive with --bbox, --use-source-
↪timestamp
  --use-source-timestamp             Use timestamp of VRT or GTI sources as refresh␣
↪criterion
                                     Mutually exclusive with --bbox, --like

Advanced Options:
  --oo, --open-option <KEY>=<VALUE>  Open options [may be repeated]
```

Description

gdal raster overview refresh can be used to refresh existing overviews of a dataset. By default all overviews are refreshed, but it is also possible to restrict the refreshed overviews by level and/or extent.

Program-Specific Options

--bbox `<xmin>,<ymin>,<xmax>,ymax>`

This option performs a partial refresh of existing overviews, in the region of interest specified by georeferenced coordinates, in CRS units.

'x' is longitude values for geographic CRS and easting for projected CRS. 'y' is latitude values for geographic CRS and northing for projected CRS.

--dataset `<DATASET>`

Dataset name, to be updated in-place by default (unless *--external* is specified). Required.

--external

Refresh external `.ovr` overviews.

--levels `<level1,level2,...>`

A list of overview levels to build. Each overview level must be an integer value greater or equal to 2.

If not specified all existing overviews are refreshed.

--like `<filename1>[,<filenameN>]...`

This option performs a partial refresh of existing overviews, in the region of interest specified by one or several filenames (names separated by comma). Note that the filenames are only used to determine the regions of interest to refresh. The reference source pixels are the one of the main dataset. By default all existing overview levels will be refreshed, unless explicit levels are specified. See *Example 2*.

-r,
--resampling `{nearest|average|cubic|cubicspline|lanczos|bilinear|gauss|average_magphase|rms|mode}`

Select a resampling algorithm. The default is `nearest`, which is generally not appropriate if sub-pixel accuracy is desired.

When refreshing existing TIFF overviews, the previously used method, as noted in the RESAMPLING metadata item of the overview, will be used if *-r* is not specified.

The available methods are:

`nearest` applies a nearest neighbour (simple sampling) resampler.

`average` computes the average of all non-NODATA contributing pixels. This is a weighted average taking into account properly the weight of source pixels not contributing fully to the target pixel.

`bilinear` applies a bilinear convolution kernel.

`cubic` applies a cubic convolution kernel.

`cubicspline` applies a B-Spline convolution kernel.

`lanczos` applies a Lanczos windowed sinc convolution kernel.

`gauss` applies a Gaussian kernel before computing the overview, which can lead to better results than simple averaging in e.g case of sharp edges with high contrast or noisy patterns. The advised level values should be 2, 4, 8, ... so that a 3x3 resampling Gaussian kernel is selected.

`average_magphase` averages complex data in mag/phase space.

`rms` computes the root mean squared / quadratic mean of all non-NODATA contributing pixels

`mode` selects the value which appears most often of all the sampled points.

--use-source-timestamp

This option performs a partial refresh of existing overviews of a *VRT -- GDAL Virtual Format* or *GTI -- GDAL Raster Tile Index* file with an external overview. It checks the modification timestamp of all the sources of the VRT and regenerate the overview for areas corresponding to sources whose timestamp is more recent than the external overview of the VRT. By default all existing overview levels will be refreshed, unless explicit levels are specified. See *Example 1*.

Standard Options

--oo, --open-option <NAME>=<VALUE>

Dataset open option (format specific).

May be repeated.

Return status code

The program returns status code 0 in case of success, and non-zero in case of error (non-blocking errors emitted as warnings are considered as a successful execution).

Examples

Example 1: Refresh external overviews of a VRT file using timestamp of source files

This is needed when for sources have been modified after the .vrt.ovr generation:

```
gdal raster mosaic tile1.tif tile2.tif my.vrt              # create VRT
gdal raster overview add --external -r cubic my.vrt        # initial overview generation
touch tile1.tif                                            # simulate update of one of␣
↪the source tiles
gdal raster overview refresh --external -r cubic \
                          --use-source-timestamp my.vrt    # refresh overviews
```

Example 2: Refresh (internal) overviews of a TIFF file

```
gdal raster mosaic tile1.tif tile2.tif mosaic.tif       # create mosaic
gdal raster overview add -r cubic mosaic.tif            # initial overview generation
gdalwarp tile1_modif.tif mosaic.tif                     # update mosaic
gdal raster overview refresh --like=tile1.tif my.tif    # refresh overviews
```

5.1.3.27 gdal raster pansharpen

Added in version 3.12.

Synopsis

```
Usage: gdal raster pansharpen [OPTIONS] <INPUT> <SPECTRAL>... <OUTPUT>

Perform a pansharpen operation.

Positional arguments:
  -i, --panchromatic, --input <INPUT>                      Input panchromatic raster␣
↪dataset [required] [not available in pipelines]
  --spectral <SPECTRAL>                                    Input spectral band dataset␣
↪[1.. values] [required]
  -o, --output <OUTPUT>                                    Output raster dataset␣
↪[required] [not available in pipelines]

↪repeated] [not available in pipelines]
  --overwrite                                              Whether overwriting existing␣
↪output dataset is allowed [not available in pipelines]
                                                           Mutually exclusive with --
↪append
  --append                                                 Append as a subdataset to␣
↪existing output [not available in pipelines]
                                                           Mutually exclusive with --
↪overwrite
  -r, --resampling <RESAMPLING>                            Resampling algorithm.␣
↪RESAMPLING=nearest|bilinear|cubic|cubicspline|lanczos|average (default: cubic)
  --weights <WEIGHTS>                                      Weight for each input␣
↪spectral band [may be repeated]
  --nodata <NODATA>                                        Override nodata value of␣
↪input bands
```

(continues on next page)

(continued from previous page)

```
  --bit-depth <BIT-DEPTH>                                  Override bit depth of input␣
↪bands
  --spatial-extent-adjustment <SPATIAL-EXTENT-ADJUSTMENT>  Select behavior when bands␣
↪have not the same extent. SPATIAL-EXTENT-ADJUSTMENT=union|intersection|none|none-
↪without-warning (default: union)
  -j, --num-threads <NUM-THREADS>                          Number of jobs (or ALL_CPUS)␣
↪(default: ALL_CPUS)

Advanced Options:
  --if, --input-format <INPUT-FORMAT>                      Input formats [may be␣
↪repeated] [not available in pipelines]
  --oo, --open-option <KEY>=<VALUE>                        Open options [may be␣
↪repeated] [not available in pipelines]
```

Description

gdal raster pansharpen performs a pan-sharpening operation. It can create a "classic" output dataset (such as GeoTIFF), or a VRT dataset describing the pan-sharpening operation.

It takes as input a one-band panchromatic dataset and several spectral bands, generally at a lower resolution than the panchromatic band. The output is a multi-band dataset (with as many bands as input panchromatic bands), enhanced at the resolution of the panchromatic band.

All bands should be in the same coordinate reference system.

More details can be found in the *Pansharpened VRT* section.

GDALG output (on-the-fly / streamed dataset)

This program supports serializing the command line as a JSON file using the `GDALG` output format. The resulting file can then be opened as a raster dataset using the *GDALG: GDAL Streamed Algorithm* driver, and apply the specified pipeline in a on-the-fly / streamed way.

Program-Specific Options

--bit-depth <val>

Specify the bit depth of the panchromatic and spectral bands (e.g. 12). If not specified, the NBITS metadata item from the panchromatic band will be used if it exists.

-i, --panchromatic, --input <INPUT>

Dataset with panchromatic band. [required]

-j, --num-threads <value>

Specify number of threads to use to do the resampling and pan-sharpening itself. Can be an integer number or `ALL_CPUS` (the default)

--nodata <val>

Specify nodata value for bands. Used for the resampling and pan-sharpening computation itself. If not set, deduced from the input bands, provided they have a consistent setting.

-r, --resampling `nearest|bilinear|cubic|cubicspline|lanczos|average`

Select a resampling algorithm. `cubic` is the default.

--spatial-extent-adjustment union|intersection|none|none-without-warning

Select behavior when bands have not the same extent. See *SpatialExtentAdjustment* documentation in *Pansharpened VRT* union is the default.

--spectral <spectral_dataset>[,band=<num>]

Dataset with one or several spectral bands. [required]

If the band option is not specified, all bands of the dataset are taken into account. Otherwise, only the specified (num)th band. The same dataset can be repeated several times.

--weights <WEIGHTS>

Specify a weight for the computation of the pseudo panchromatic value. There must be as many values as input spectral bands.

Standard Options

--append

Append input raster as a new subdataset to an existing output file. Only works with drivers that support adding subdatasets such as *GTiff -- GeoTIFF File Format* and *GPKG -- GeoPackage raster* This also creates the output dataset if it does not exist yet.

--co, --creation-option <NAME>=<VALUE>

Many formats have one or more optional creation options that can be used to control particulars about the file created. For instance, the GeoTIFF driver supports creation options to control compression, and whether the file should be tiled.

May be repeated.

The creation options available vary by format driver, and some simple formats have no creation options at all. A list of options supported for a format can be listed with the *--formats* command line option but the documentation for the format is the definitive source of information on driver creation options. See *Raster drivers* format specific documentation for legal creation options for each format.

--if, --input-format <format>

Format/driver name to be attempted to open the input file(s). It is generally not necessary to specify it, but it can be used to skip automatic driver detection, when it fails to select the appropriate driver. This option can be repeated several times to specify several candidate drivers. Note that it does not force those drivers to open the dataset. In particular, some drivers have requirements on file extensions.

May be repeated.

--oo, --open-option <NAME>=<VALUE>

Dataset open option (format specific).

May be repeated.

-f, --of, --format, --output-format <OUTPUT-FORMAT>

Which output raster format to use. Allowed values may be given by `gdal --formats | grep raster | grep rw | sort`

--overwrite

Allow program to overwrite existing target file or dataset. Otherwise, by default, **gdal** errors out if the target file or dataset already exists.

Return status code

The program returns status code 0 in case of success, and non-zero in case of error (non-blocking errors emitted as warnings are considered as a successful execution).

Examples

Example 1: With spectral bands in a single dataset

```
gdal raster pansharpen panchro.tif rgb.tif pansharpened_out.tif
```

Example 2: With a few spectral bands from a single dataset, reordered

```
gdal raster pansharpen panchro.tif bgr.tif,band=3 bgr.tif,band=2 bgr.tif,band=1␣
↪pansharpened_out.tif
```

Example 3: With spectral bands in several datasets

```
gdal raster pansharpen panchro.tif red.tif green.tif blue.tif pansharpened_out.tif
```

Example 4: Specifying weights

```
gdal raster pansharpen -w 0.7,0.2,0.1 panchro.tif multispectral.tif pansharpened_out.tif
```

Example 5: Select RGB bands from a RGBNir multispectral dataset while computing the pseudo panchromatic intensity on the 4 RGBNir bands

```
gdal raster pipeline read panchro.tif ! pansharpen rgbnir.tif ! select 1,2,3 ! write␣
↪pansharpened_out.tif
```

5.1.3.28 `gdal raster pipeline`

Added in version 3.11.

Description

`gdal raster pipeline` can be used to process a raster dataset and perform various processing steps that accept raster and generate raster.

For pipelines mixing raster and vector, consult *gdal pipeline*.

Most steps proceed in on-demand evaluation of raster blocks, unless otherwise stated in their documentation, without "materializing" the resulting dataset of the operation of each step. It may be desirable sometimes for performance purposes to proceed to materializing an intermediate dataset to disk using *gdal raster materialize*.

Synopsis

```
Usage: gdal raster pipeline [OPTIONS] <PIPELINE>

Process a raster dataset applying several steps.
```

(continues on next page)

(continued from previous page)

```
Positional arguments:

Common Options:
  -h, --help              Display help message and exit
  --json-usage            Display usage as JSON document and exit
  --config <KEY>=<VALUE>  Configuration option [may be repeated]
  -q, --quiet             Quiet mode (no progress bar or warning message) [not available␣
↪in pipelines]

<PIPELINE> is of the form: read|mosaic|stack [READ-OPTIONS] ( ! <STEP-NAME> [STEP-
↪OPTIONS] )* ! info|compare|tile|write [WRITE-OPTIONS]
```

A pipeline chains several steps, separated with the *!* (exclamation mark) character. The first step must be `read`, `calc`, `create`, `mosaic` or `stack`, and the last one `write`, `info` or `tile`. Each step has its own positional or non-positional arguments. Apart from `read`, `calc`, `mosaic`, `stack`, `compare`, `info`, `tile` and `write`, all other steps can potentially be used several times in a pipeline.

Steps

- *aspect*
- *blend*
- *calc*
- *clip*
- *color-map*
- *compare*
- *create*
- *edit*
- *external*
- *fill-nodata*
- *hillshade*
- *info*
- *materialize*
- *mosaic*
- *neighbors*
- *nodata-to-alpha*
- *overview*
- *pansharpen*
- *proximity*
- *read*
- *reclassify*

- *reproject*
- *resize*
- *rgb-to-palette*
- *roughness*

- *select*
- *set-type*
- *sieve*
- *slope*
- *stack*
- *tee*
- *tile*
- *tpi*
- *tri*
- *unscale*
- *update*
- *viewshed*
- *write*

aspect

```
* aspect [OPTIONS]
------------------

Generate an aspect map

Options:
  -b, --band <BAND>              Input band (1-based index) (default: 1)
  --convention <CONVENTION>      Convention for output angles.␣
↪CONVENTION=azimuth|trigonometric-angle (default: azimuth)
  --gradient-alg <GRADIENT-ALG>  Algorithm used to compute terrain gradient. GRADIENT-
↪ALG=Horn|ZevenbergenThorne (default: Horn)
  --zero-for-flat                Whether to output zero for flat areas
  --no-edges                     Do not try to interpolate values at dataset edges or␣
↪close to nodata values
```

Details for options can be found in *gdal raster aspect*.

blend

```
* blend [OPTIONS] <OVERLAY>
---------------------------
```

(continues on next page)

(continued from previous page)

```
Blend/compose two raster datasets

Positional arguments:
  --overlay <OVERLAY>     Overlay dataset [required]

Options:
  --operator <OPERATOR>   Composition operator. OPERATOR=src-over|hsv-
↪value|multiply|screen|overlay|hard-light|darken|lighten|color-dodge|color-burn␣
↪(default: src-over)
  --opacity <OPACITY>     Opacity percentage to apply to the overlay dataset (0=fully␣
↪transparent, 100=full use of overlay opacity) (default: 100)
```

Details for options can be found in *gdal raster blend*.

calc

```
* calc [OPTIONS] <INPUTS>...
----------------------------

Perform raster algebra

Positional arguments:
  -i, --input <INPUTS>                                    Input raster datasets [1..␣
↪values] [required]

Options:
  --ot, --datatype, --output-data-type <OUTPUT-DATA-TYPE>  Output data type. OUTPUT-DATA-
↪TYPE=UInt8|Int8|UInt16|Int16|UInt32|Int32|UInt64|Int64|CInt16|CInt32|Float16|Float32|Float64|CFloat32
  --no-check-crs                                          Do not check consistency of␣
↪input coordinate reference systems
  --no-check-extent                                       Do not check consistency of␣
↪input extents
  --propagate-nodata                                      Whether to set pixels to the␣
↪output NoData value if any of the input pixels is NoData
  --calc <CALC>                                           Expression(s) to evaluate [1..
↪ values] [required]
  --dialect <DIALECT>                                     Expression dialect.␣
↪DIALECT=muparser|builtin (default: muparser)
  --flatten                                               Generate a single band output␣
↪raster per expression, even if input datasets are multiband
  --nodata <NODATA>                                       Assign a specified nodata␣
↪value to output bands ('none', numeric value, 'nan', 'inf', '-inf')

Advanced Options:
  --if, --input-format <INPUT-FORMAT>                     Input formats [may be␣
↪repeated]
  --oo, --open-option <KEY>=<VALUE>                       Open options [may be repeated]
```

Details for options can be found in *gdal raster calc*.

clip

```
* clip [OPTIONS]
----------------

Clip a raster dataset.

Options:
  --bbox <BBOX>                    Clipping bounding box as xmin,ymin,xmax,ymax
                                   Mutually exclusive with --window, --geometry, --like
  --bbox-crs <BBOX-CRS>            CRS of clipping bounding box
  --window <WINDOW>                Raster window as col,line,width,height in pixels
                                   Mutually exclusive with --bbox, --geometry, --like
  --geometry <GEOMETRY>            Clipping geometry (WKT or GeoJSON)
                                   Mutually exclusive with --bbox, --window, --like
  --geometry-crs <GEOMETRY-CRS>    CRS of clipping geometry
  --like <DATASET>                 Dataset to use as a template for bounds
                                   Mutually exclusive with --bbox, --window, --geometry
  --like-sql <SELECT-STATEMENT>    SELECT statement to run on the 'like' dataset
                                   Mutually exclusive with --like-where
  --like-layer <LAYER-NAME>        Name of the layer of the 'like' dataset
  --like-where <WHERE-EXPRESSION>  WHERE SQL clause to run on the 'like' dataset
                                   Mutually exclusive with --like-sql
  --only-bbox                      For 'geometry' and 'like', only consider their␣
↪bounding box
  --allow-bbox-outside-source      Allow clipping box to include pixels outside input␣
↪dataset
  --add-alpha                      Adds an alpha mask band to the destination when the␣
↪source raster have none.
```

Details for options can be found in *gdal raster clip*.

color-map

```
* color-map [OPTIONS]
---------------------

Generate a RGB or RGBA dataset from a single band, using a color map

Options:
  -b, --band <BAND>                    Input band (1-based index) (default: 1)
  --color-map <COLOR-MAP>              Color map filename
  --add-alpha                          Adds an alpha mask band to the destination.
  --color-selection <COLOR-SELECTION>  How to compute output colors from input values.␣
↪COLOR-SELECTION=interpolate|exact|nearest (default: interpolate)
```

Details for options can be found in *gdal raster color-map*.

compare

Added in version 3.12.

```
* compare [OPTIONS] <REFERENCE>
------------------------------

Compare two raster datasets.

Positional arguments:
  --reference <REFERENCE>  Reference dataset [required]

Options:
  --skip-all-optional      Skip all optional comparisons
  --skip-binary            Skip binary file comparison
  --skip-crs               Skip CRS comparison
  --skip-geotransform      Skip geotransform comparison
  --skip-overview          Skip overview comparison
  --skip-metadata          Skip metadata comparison
  --skip-rpc               Skip RPC metadata comparison
  --skip-geolocation       Skip Geolocation metadata comparison
  --skip-subdataset        Skip subdataset comparison
```

Details for options can be found in *gdal raster compare*.

create

```
* create [OPTIONS]
------------------

Create a new raster dataset.

Options:
  -i, --like, --input <TEMPLATE-DATASET>                   Template raster dataset
  --size <width>,<height>                                   Output size in pixels
  --band-count <BAND-COUNT>                                 Number of bands (default: 1)
  --ot, --datatype, --output-data-type <OUTPUT-DATA-TYPE>  Output data type. OUTPUT-DATA-
↪TYPE=UInt8|Int8|UInt16|Int16|UInt32|Int32|UInt64|Int64|CInt16|CInt32|Float16|Float32|Float64|CFloat32
↪(default: Byte)
  --nodata <NODATA>                                         Assign a specified nodata␣
↪value to output bands ('none', numeric value, 'nan', 'inf', '-inf')
  --burn <BURN>                                             Burn value [may be repeated]
  --crs <CRS>                                               Set CRS
  --bbox <BBOX>                                             Bounding box as xmin,ymin,
↪xmax,ymax
  --metadata <KEY>=<VALUE>                                  Add metadata item [may be␣
↪repeated]
  --copy-metadata                                           Copy metadata from input␣
↪dataset
                                                            Depends on --input
  --copy-overviews                                          Create same overview levels␣
↪as input dataset
                                                            Depends on --input

Advanced Options:
  --if, --input-format <INPUT-FORMAT>                       Input formats [may be␣
```

(continues on next page)

(continued from previous page)

```
↪repeated]
  --oo, --open-option <KEY>=<VALUE>                        Open options [may be repeated]
```

Details for options can be found in *gdal raster create*.

edit

```
* edit [OPTIONS]
----------------

Edit a raster dataset.

Options:
  -b, --band <BAND>                                        Active band (1-based index)
  --crs <CRS>                                              Override CRS (without␣
↪reprojection)
  --bbox <BBOX>                                            Bounding box as xmin,ymin,
↪xmax,ymax
  --nodata <NODATA>                                        Assign a specified nodata␣
↪value to output bands ('none', numeric value, 'nan', 'inf', '-inf')
  --color-interpretation <[all|<BAND>=]<COLOR-INTEPRETATION>  Set band color␣
↪interpretation [may be repeated]
  --color-map <COLOR-MAP>                                  Color map filename
                                                           Mutually exclusive with --
↪unset-color-table
  --scale <[<BAND>=]<SCALE>                                Override band scale factor␣
↪[may be repeated]
  --offset <[<BAND>=]<OFFSET>                              Override band offset␣
↪constant [may be repeated]
  --metadata <KEY>=<VALUE>                                 Add/update dataset␣
↪metadata item [may be repeated]
  --unset-color-table                                      Unset color table on 1st␣
↪band or the one specified with --band
                                                           Mutually exclusive with --
↪color-map
  --unset-metadata <KEY>                                   Remove dataset metadata␣
↪item(s) [may be repeated]
  --unset-metadata-domain <DOMAIN>                         Remove dataset metadata␣
↪domain(s) [may be repeated]
  --gcp <GCP>                                              Add ground control point,␣
↪formatted as pixel,line,easting,northing[,elevation], or @filename [may be repeated]
```

Details for options can be found in *gdal raster edit*.

external

```
* external [OPTIONS] <COMMAND>
------------------------------

Execute an external program as a step of a pipeline
```

(continues on next page)

(continued from previous page)

```
Positional arguments:
  --command <COMMAND>                                External command, optionally with
↪<INPUT> and/or <OUTPUT> or <INPUT-OUTPUT> placeholders [required]

Options:
  -f, --of, --format, --output-format <OUTPUT-FORMAT>  Output format

Advanced Options:
  --if, --input-format <INPUT-FORMAT>                  Input formats
```

Details for options can be found in *gdal external*.

fill-nodata

```
* fill-nodata [OPTIONS]
-----------------------

Fill nodata raster regions by interpolation from edges.

Options:
  -b, --band <BAND>                                  Input band (1-based index)␣
↪(default: 1)
  -d, --max-distance <MAX_DISTANCE>                  The maximum distance (in pixels)␣
↪that the algorithm will search out for values to interpolate. (default: 100)
  -s, --smoothing-iterations <SMOOTHING_ITERATIONS>  The number of 3x3 average filter␣
↪smoothing iterations to run after the interpolation to dampen artifacts. The default␣
↪is zero smoothing iterations. (default: 0)
  --mask <MASK>                                      Use the first band of the specified␣
↪file as a validity mask (zero is invalid, non-zero is valid).
  --strategy <STRATEGY>                              By default, pixels are interpolated␣
↪using an inverse distance weighting (invdist). It is also possible to choose a nearest␣
↪neighbour (nearest) strategy.. STRATEGY=invdist|nearest (default: invdist)
```

Details for options can be found in *gdal raster fill-nodata*.

hillshade

```
* hillshade [OPTIONS]
---------------------

Generate a shaded relief map

Options:
  -b, --band <BAND>              Input band (1-based index) (default: 1)
  -z, --zfactor <ZFACTOR>        Vertical exaggeration used to pre-multiply the␣
↪elevations
  --xscale <XSCALE>              Ratio of vertical units to horizontal X axis units
  --yscale <YSCALE>              Ratio of vertical units to horizontal Y axis units
  --azimuth <AZIMUTH>            Azimuth of the light, in degrees (default: 315)
  --altitude <ALTITUDE>          Altitude of the light, in degrees (default: 45)
  --gradient-alg <GRADIENT-ALG>  Algorithm used to compute terrain gradient. GRADIENT-
```

(continues on next page)

(continued from previous page)

```
↪ALG=Horn|ZevenbergenThorne (default: Horn)
  --variant <VARIANT>            Variant of the hillshading algorithm.␣
↪VARIANT=regular|combined|multidirectional|Igor (default: regular)
  --no-edges                     Do not try to interpolate values at dataset edges or␣
↪close to nodata values
```

Details for options can be found in *gdal raster hillshade*.

info

Added in version 3.12.

```
* info [OPTIONS]
----------------

Return information on a raster dataset.

Options:
  -f, --of, --format, --output-format <OUTPUT-FORMAT>  Output format. OUTPUT-
↪FORMAT=json|text
  --mm, --min-max                                      Compute minimum and maximum value
  --stats                                              Retrieve or compute statistics,␣
↪using all pixels
                                                       Mutually exclusive with --approx-
↪stats
  --approx-stats                                       Retrieve or compute statistics,␣
↪using a subset of pixels
                                                       Mutually exclusive with --stats
  --hist                                               Retrieve or compute histogram

Advanced Options:
  --no-gcp                                             Suppress ground control points␣
↪list printing
  --no-md                                              Suppress metadata printing
  --no-ct                                              Suppress color table printing
  --no-fl                                              Suppress file list printing
  --checksum                                           Compute pixel checksum
  --list-metadata-domains, --list-mdd                  List all metadata domains␣
↪available for the dataset
  --mdd, --metadata-domain <METADATA-DOMAIN>           Report metadata for the specified␣
↪domain. 'all' can be used to report metadata in all domains

Esoteric Options:
  --no-nodata                                          Suppress retrieving nodata value
  --no-mask                                            Suppress mask band information
  --subdataset <SUBDATASET>                            Use subdataset of specified index␣
↪(starting at 1), instead of the source dataset itself
  --crs-format <CRS-FORMAT>                            Which format to use to report CRS.
↪ CRS-FORMAT=AUTO|WKT2|PROJJSON (default: AUTO)
```

Details for options can be found in *gdal raster info*.

materialize

```
* materialize [OPTIONS]
-----------------------

Materialize a piped dataset on disk to increase the efficiency of the following steps.

Options:
  -o, --output <OUTPUT>                                Materialized dataset name␣
↪(created by algorithm)
  -f, --of, --format, --output-format <OUTPUT-FORMAT>  Output format
  --co, --creation-option <KEY>=<VALUE>                Creation option [may be repeated]
  --overwrite                                          Whether overwriting existing␣
↪output dataset is allowed
```

Details for options can be found in *gdal raster materialize*.

mosaic

```
* mosaic [OPTIONS] <INPUTS>...
------------------------------

Build a mosaic, either virtual (VRT) or materialized.

Positional arguments:
  -i, --input <INPUTS>                                          Input raster datasets␣
↪(or specify a @<filename> to point to a file containing filenames) [1.. values]␣
↪[required]

Options:
  -b, --band <BAND>                                             Input band(s) (1-based␣
↪index) [may be repeated]
  --absolute-path                                               Whether the path to␣
↪the input datasets should be stored as an absolute path
  --resolution <xres>,<yres>|same|average|common|highest|lowest>  Target resolution (in␣
↪destination CRS units) (default: same)
  --bbox <BBOX>                                                 Target bounding box as␣
↪xmin,ymin,xmax,ymax (in destination CRS units)
  --target-aligned-pixels                                       Round target extent to␣
↪target resolution
  --input-nodata <INPUT-NODATA>                                 Set nodata values for␣
↪input bands. [1.. values]
  --output-nodata <OUTPUT-NODATA>                               Set nodata values at␣
↪the destination band level. [1.. values]
  --hide-nodata                                                 Makes the destination␣
↪band not report the NoData.
  --add-alpha                                                   Adds an alpha mask␣
↪band to the destination when the source raster have none.
  --pixel-function <PIXEL-FUNCTION>                             Specify a pixel␣
↪function to calculate output value from overlapping inputs. PIXEL-
↪FUNCTION=abs|area|argmax|argmin|cmul|complex|conj|dB|dB2amp|dB2pow|diff|div|exp|expression|geometric_
↪mean|harmonic_mean|imag|intensity|interpolate_exp|interpolate_
↪linear|inv|log10|max|mean|median|min|mod|mode|mul|norm_
```

(continues on next page)

(continued from previous page)

```
↪diff|phase|polar|pow|quantile|real|reclassify|replace_nodata|round|scale|sqrt|sum
  --pixel-function-arg <NAME>=<VALUE>                              Specify argument(s) to␣
↪pass to the pixel function [may be repeated]

Advanced Options:
  --if, --input-format <INPUT-FORMAT>                              Input formats [may be␣
↪repeated]
  --oo, --open-option <KEY>=<VALUE>                                Open options [may be␣
↪repeated]
```

Details for options can be found in *gdal raster mosaic*.

neighbors

```
* neighbors [OPTIONS]
---------------------

Compute the value of each pixel from its neighbors (focal statistics)

Options:
  -b, --band <BAND>                                        Input band (1-based index)
  --method <METHOD>                                        Method to combine weighed␣
↪source pixels. METHOD=mean|sum|min|max|stddev|median|mode [may be repeated]
  --size <SIZE>                                            Neighborhood size
  --kernel <KERNEL>                                        Convolution kernel(s) to␣
↪apply [1.. values] [required]
  --ot, --datatype, --output-data-type <OUTPUT-DATA-TYPE>  Output data type. OUTPUT-DATA-
↪TYPE=UInt8|Int8|UInt16|Int16|UInt32|Int32|UInt64|Int64|CInt16|CInt32|Float16|Float32|Float64|CFloat32
↪(default: Float64)
  --nodata <NODATA>                                        Assign a specified nodata␣
↪value to output bands ('none', numeric value, 'nan', 'inf', '-inf')
```

Details for options can be found in *gdal raster neighbors*.

nodata-to-alpha

```
* nodata-to-alpha [OPTIONS]
---------------------------

Replace nodata value(s) with an alpha band.

Options:
  --nodata <NODATA>       Override nodata value of input band(s) (numeric value, 'nan',
↪'inf', '-inf') [may be repeated]
```

Details for options can be found in *gdal raster nodata-to-alpha*.

overview

```
* overview <COMMAND> [OPTIONS]
------------------------------
```

(continues on next page)

(continued from previous page)

```
where <COMMAND> is one of:
  - add: Adding overviews.
```

Details for options can be found in *gdal raster overview*.

pansharpen

```
* pansharpen [OPTIONS] <SPECTRAL>...
-----------------------------------

Perform a pansharpen operation.

Positional arguments:
  --spectral <SPECTRAL>                                   Input spectral band dataset␣
↪[1.. values] [required]

Options:
  -r, --resampling <RESAMPLING>                           Resampling algorithm.␣
↪RESAMPLING=nearest|bilinear|cubic|cubicspline|lanczos|average (default: cubic)
  --weights <WEIGHTS>                                     Weight for each input␣
↪spectral band [may be repeated]
  --nodata <NODATA>                                       Override nodata value of␣
↪input bands
  --bit-depth <BIT-DEPTH>                                 Override bit depth of input␣
↪bands
  --spatial-extent-adjustment <SPATIAL-EXTENT-ADJUSTMENT>  Select behavior when bands␣
↪have not the same extent. SPATIAL-EXTENT-ADJUSTMENT=union|intersection|none|none-
↪without-warning (default: union)
  -j, --num-threads <NUM-THREADS>                         Number of jobs (or ALL_CPUS)␣
↪(default: ALL_CPUS)
```

Details for options can be found in *gdal raster pansharpen*.

proximity

```
* proximity [OPTIONS]
---------------------

Produces a raster proximity map.

Options:
  --ot, --datatype, --output-data-type <OUTPUT-DATA-TYPE>  Output data type. OUTPUT-DATA-
↪TYPE=UInt8|Int8|UInt16|Int16|UInt32|Int32|UInt64|Int64|CInt16|CInt32|Float16|Float32|Float64|CFloat32
↪(default: Float32)
  -b, --band <BAND>                                       Input band (1-based index)
  --target-values <TARGET-VALUES>                         Target pixel values [may be␣
↪repeated]
  --distance-units <DISTANCE-UNITS>                       Distance units. DISTANCE-
↪UNITS=pixel|geo (default: pixel)
  --max-distance <MAX-DISTANCE>                           Maximum distance. The nodata␣
```

(continues on next page)

(continued from previous page)

```
↪value will be used for pixels beyond this distance (default: 0)
  --fixed-value <FIXED-VALUE>                              Fixed value for the pixels␣
↪that are within the maximum distance (instead of the actual distance) (default: 0)
  --nodata <NODATA>                                        Specify a nodata value to use␣
↪for pixels that are beyond the maximum distance
```

Details for options can be found in *gdal raster proximity*.

read

```
* read [OPTIONS] <INPUT>
------------------------

Read a raster dataset.

Positional arguments:
  -i, --input <INPUT>                  Input raster datasets [required]

Advanced Options:
  --if, --input-format <INPUT-FORMAT>  Input formats [may be repeated]
  --oo, --open-option <KEY>=<VALUE>    Open options [may be repeated]
```

Details for options can be found in *gdal raster pipeline read*.

reclassify

```
* reclassify [OPTIONS]
----------------------

Reclassify values in a raster dataset

Options:
  -m, --mapping <MAPPING>                                  Reclassification mappings (or␣
↪specify a @<filename> to point to a file containing mappings [required]
  --ot, --datatype, --output-data-type <OUTPUT-DATA-TYPE>  Output data type. OUTPUT-DATA-
↪TYPE=UInt8|Int8|UInt16|Int16|UInt32|Int32|UInt64|Int64|CInt16|CInt32|Float16|Float32|Float64|CFloat32
```

Details for options can be found in *gdal raster reclassify*.

reproject

```
* reproject [OPTIONS]
---------------------

Reproject a raster dataset.

Options:
  -s, --input-crs <INPUT-CRS>                Input CRS
  --like <DATASET>                           Dataset to use as a template for target␣
↪bounds, CRS, size and nodata
  -d, --output-crs <OUTPUT-CRS>              Output CRS
```

(continues on next page)

(continued from previous page)

```
  -r, --resampling <RESAMPLING>              Resampling method.␣
↪RESAMPLING=nearest|bilinear|cubic|cubicspline|lanczos|average|rms|mode|min|max|med|q1|q3|sum␣
↪(default: nearest)
  --resolution <xres>,<yres>                 Target resolution (in destination CRS units)
                                             Mutually exclusive with --size
  --size <width>,<height>                    Target size in pixels
                                             Mutually exclusive with --resolution
  --bbox <BBOX>                              Target bounding box (in destination CRS␣
↪units)
  --bbox-crs <BBOX-CRS>                      CRS of target bounding box
  -j, --num-threads <NUM-THREADS>            Number of jobs (or ALL_CPUS) (default: ALL_
↪CPUS)

Advanced Options:
  --target-aligned-pixels                    Round target extent to target resolution
  --input-nodata <INPUT-NODATA>              Set nodata values for input bands ('None'␣
↪to unset). [1.. values]
  --output-nodata <OUTPUT-NODATA>            Set nodata values for output bands ('None'␣
↪to unset). [1.. values]
  --add-alpha                                Adds an alpha mask band to the destination␣
↪when the source raster have none.
  --wo, --warp-option <NAME>=<VALUE>         Warping option(s) [may be repeated]
  --to, --transform-option <NAME>=<VALUE>    Transform option(s) [may be repeated]
  --et, --error-threshold <ERROR-THRESHOLD>  Error threshold
```

Details for options can be found in *gdal raster reproject*.

resize

```
* resize [OPTIONS]
------------------

Resize a raster dataset without changing the georeferenced extents.

Options:
  --resolution <xres>,<yres>     Target resolution (in destination CRS units)
                                 Mutually exclusive with --size
  --size <width[%]>,<height[%]>  Target size in pixels (or percentage if using '%'␣
↪suffix) [required]
                                 Mutually exclusive with --resolution
  -r, --resampling <RESAMPLING>  Resampling method.␣
↪RESAMPLING=nearest|bilinear|cubic|cubicspline|lanczos|average|mode (default: nearest)
```

Details for options can be found in *gdal raster resize*.

rgb-to-palette

```
* rgb-to-palette [OPTIONS]
--------------------------

Convert a RGB image into a pseudo-color / paletted image.
```

(continues on next page)

(continued from previous page)

```
Options:
  --color-count <COLOR-COUNT>      Select the number of colors in the generated color␣
↪table (default: 256)
  --color-map <COLOR-MAP>          Color map filename
  --output-nodata <OUTPUT-NODATA>  Output nodata value
  --no-dither                      Disable Floyd-Steinberg dithering
  --bit-depth <BIT-DEPTH>          Bit depth of color palette component (8 bit causes␣
↪longer computation time). BIT-DEPTH=5|8 (default: 5)
```

Details for options can be found in *gdal raster rgb-to-palette*.

roughness

```
* roughness [OPTIONS]
---------------------

Generate a roughness map

Options:
  -b, --band <BAND>       Input band (1-based index) (default: 1)
  --no-edges              Do not try to interpolate values at dataset edges or close to␣
↪nodata values
```

Details for options can be found in *gdal raster roughness*.

scale

```
* scale [OPTIONS]
-----------------

Scale the values of the bands of a raster dataset.

Options:
  --ot, --datatype, --output-data-type <OUTPUT-DATA-TYPE>  Output data type. OUTPUT-DATA-
↪TYPE=UInt8|Int8|UInt16|Int16|UInt32|Int32|UInt64|Int64|CInt16|CInt32|Float16|Float32|Float64|CFloat32
  -b, --band <BAND>                                        Select band to restrict the␣
↪scaling (1-based index)
  --input-min <INPUT-MIN>                                  Minimum value of the source␣
↪range
                                                           Depends on --input-max
  --input-max <INPUT-MAX>                                  Maximum value of the source␣
↪range
                                                           Depends on --input-min
  --output-min <OUTPUT-MIN>                                Minimum value of the␣
↪destination range
                                                           Depends on --output-max
  --output-max <OUTPUT-MAX>                                Maximum value of the␣
↪destination range
                                                           Depends on --output-min
  --exponent <EXPONENT>                                    Exponent to apply non-linear␣
```

(continues on next page)

(continued from previous page)

```
↪scaling with a power function
  --no-clip                                                Do not clip input values to␣
↪[innput-min, input-max]
```

Details for options can be found in *gdal raster scale*.

select

```
* select [OPTIONS] <BAND>
-------------------------

Select a subset of bands from a raster dataset.

Positional arguments:
  -b, --band <BAND>       Band(s) (1-based index, 'mask', 'mask:<band>' or color␣
↪interpretation such as 'red') [1.. values] [required]

Options:
  --exclude               Exclude specified bands
  --mask <MASK>           Mask band (1-based index, 'mask', 'mask:<band>' or 'none')
```

Details for options can be found in *gdal raster select*.

set-type

```
* set-type [OPTIONS]
--------------------

Modify the data type of bands of a raster dataset.

Options:
  --ot, --datatype, --output-data-type <OUTPUT-DATA-TYPE>  Output data type. OUTPUT-DATA-
↪TYPE=UInt8|Int8|UInt16|Int16|UInt32|Int32|UInt64|Int64|CInt16|CInt32|Float16|Float32|Float64|CFloat32
↪[required]
```

Details for options can be found in *gdal raster set-type*.

sieve

```
* sieve [OPTIONS]
-----------------

Remove small polygons from a raster dataset.

Options:
  --mask <MASK>                          Use the first band of the specified file as a␣
↪validity mask (all pixels with a value other than zero will be considered suitable for␣
↪inclusion in polygons)
  -b, --band <BAND>                      Input band (1-based index)
  -s, --size-threshold <SIZE-THRESHOLD>  Minimum size of polygons to keep (default: 2)
  -c, --connect-diagonal-pixels          Consider diagonal pixels as connected
```

Details for options can be found in *gdal raster sieve*.

slope

```
* slope [OPTIONS]
-----------------

Generate a slope map

Options:
  -b, --band <BAND>              Input band (1-based index) (default: 1)
  --unit <UNIT>                  Unit in which to express slopes. UNIT=degree|percent␣
↪(default: degree)
  --xscale <XSCALE>              Ratio of vertical units to horizontal X axis units
  --yscale <YSCALE>              Ratio of vertical units to horizontal Y axis units
  --gradient-alg <GRADIENT-ALG>  Algorithm used to compute terrain gradient. GRADIENT-
↪ALG=Horn|ZevenbergenThorne (default: Horn)
  --no-edges                     Do not try to interpolate values at dataset edges or␣
↪close to nodata values
```

Details for options can be found in *gdal raster slope*.

stack

```
* stack [OPTIONS] <INPUTS>...
-----------------------------

Combine together input bands into a multi-band output, either virtual (VRT) or␣
↪materialized.

Positional arguments:
  -i, --input <INPUTS>                                          Input raster datasets␣
↪(or specify a @<filename> to point to a file containing filenames) [1.. values]␣
↪[required]

Options:
  -b, --band <BAND>                                             Input band(s) (1-based␣
↪index) [may be repeated]
  --absolute-path                                               Whether the path to␣
↪the input datasets should be stored as an absolute path
  --resolution <xres>,<yres>|same|average|common|highest|lowest>  Target resolution (in␣
↪destination CRS units) (default: same)
  --bbox <BBOX>                                                 Target bounding box as␣
↪xmin,ymin,xmax,ymax (in destination CRS units)
  --target-aligned-pixels                                       Round target extent to␣
↪target resolution
  --input-nodata <INPUT-NODATA>                                 Set nodata values for␣
↪input bands. [1.. values]
  --output-nodata <OUTPUT-NODATA>                               Set nodata values at␣
↪the destination band level. [1.. values]
  --hide-nodata                                                 Makes the destination␣
↪band not report the NoData.
```

(continues on next page)

(continued from previous page)

```
Advanced Options:
  --if, --input-format <INPUT-FORMAT>                              Input formats [may be␣
↪repeated]
  --oo, --open-option <KEY>=<VALUE>                                Open options [may be␣
↪repeated]
```

Details for options can be found in *gdal raster stack*.

tee

```
* tee [OPTIONS] [<PIPELINE>...]
------------------------------

Pipes the input into the output stream and side nested pipelines.

Positional arguments:
  --tee-pipeline <PIPELINE>  Nested pipeline [1.. values]
```

Details for options can be found in *Output nested pipeline*.

tile

Added in version 3.12.

```
* tile [OPTIONS] <OUTPUT>
-------------------------

Generate tiles in separate files from a raster dataset.

Positional arguments:
  -o, --output <OUTPUT>                                            Output directory␣
↪[required]

Options:
  -f, --of, --format, --output-format <OUTPUT-FORMAT>              Output format␣
↪(default: PNG)
  --co, --creation-option <KEY>=<VALUE>                            Creation option [may␣
↪be repeated]
  --tiling-scheme <TILING-SCHEME>                                  Tiling scheme. TILING-
↪SCHEME=raster|WebMercatorQuad|WorldCRS84Quad|WorldMercatorWGS84Quad|GoogleCRS84Quad|PseudoTMS_
↪GlobalMercator|GlobalGeodeticOriginLat270|LINZAntarticaMapTilegrid|APSTILE|CBMTILE|NZTM2000␣
↪(default: WebMercatorQuad)
  --min-zoom <MIN-ZOOM>                                            Minimum zoom level
  --max-zoom <MAX-ZOOM>                                            Maximum zoom level
  --min-x <MIN-X>                                                  Minimum tile X␣
↪coordinate
  --max-x <MAX-X>                                                  Maximum tile X␣
↪coordinate
  --min-y <MIN-Y>                                                  Minimum tile Y␣
↪coordinate
  --max-y <MAX-Y>                                                  Maximum tile Y␣
↪coordinate
```

(continues on next page)

(continued from previous page)

```
  --no-intersection-ok                                          Whether dataset␣
↪extent not intersecting tile matrix is only a warning
  -r, --resampling <RESAMPLING>                                 Resampling method for␣
↪max zoom.␣
↪RESAMPLING=nearest|bilinear|cubic|cubicspline|lanczos|average|rms|mode|min|max|med|q1|q3|sum␣
↪(default: cubic)
  --overview-resampling <OVERVIEW-RESAMPLING>                   Resampling method for␣
↪overviews. OVERVIEW-
↪RESAMPLING=nearest|bilinear|cubic|cubicspline|lanczos|average|rms|mode|min|max|med|q1|q3|sum
  --convention <CONVENTION>                                     Tile numbering␣
↪convention: xyz (from top) or tms (from bottom). CONVENTION=xyz|tms (default: xyz)
  --tile-size <TILE-SIZE>                                       Override default tile␣
↪size
  --add-alpha                                                   Whether to force␣
↪adding an alpha channel
                                                                Mutually exclusive␣
↪with --no-alpha
  --no-alpha                                                    Whether to disable␣
↪adding an alpha channel
                                                                Mutually exclusive␣
↪with --add-alpha
  --output-nodata <OUTPUT-NODATA>                               Output nodata value
  --skip-blank                                                  Do not generate blank␣
↪tiles
  --metadata <KEY>=<VALUE>                                      Add metadata item to␣
↪output tiles [may be repeated]
  --copy-src-metadata                                           Whether to copy␣
↪metadata from source dataset
  --aux-xml                                                     Generate .aux.xml␣
↪sidecar files when needed
  --kml                                                         Generate KML files
  --resume                                                      Generate only missing␣
↪files
  -j, --num-threads <NUM-THREADS>                               Number of jobs (or␣
↪ALL_CPUS) (default: ALL_CPUS)
  --parallel-method <PARALLEL-METHOD>                           Parallelization␣
↪method (thread, spawn, fork). PARALLEL-METHOD=thread|spawn|fork

Advanced Resampling Options:
  --excluded-values <EXCLUDED-VALUES>                           Tuples of values (e.g.
↪ <R>,<G>,<B> or (<R1>,<G1>,<B1>),(<R2>,<G2>,<B2>)) that must beignored as contributing␣
↪source pixels during (average) resampling
  --excluded-values-pct-threshold <EXCLUDED-VALUES-PCT-THRESHOLD>  Minimum percentage of␣
↪source pixels that must be set at one of the --excluded-values to cause the excluded␣
↪value to be used as the target pixel value (default: 50)
  --nodata-values-pct-threshold <NODATA-VALUES-PCT-THRESHOLD>      Minimum percentage of␣
↪source pixels that must be set at one of nodata (or alpha=0 or any other way to␣
↪express transparent pixelto cause the target pixel value to be transparent (default:␣
↪100)

Publication Options:
  --webviewer <WEBVIEWER>                                       Web viewer to␣
```

(continues on next page)

↪generated tiles are going to be published
  --title <TITLE>                                                Title of the map
  --copyright <COPYRIGHT>                                        Copyright for the map
  --mapml-template <MAPML-TEMPLATE>                              Filename of a␣
↪template mapml file where variables will be substituted
```

Details for options can be found in *gdal raster tile*.

tpi

```
* tpi [OPTIONS]
---------------

Generate a Topographic Position Index (TPI) map

Options:
  -b, --band <BAND>       Input band (1-based index) (default: 1)
  --no-edges              Do not try to interpolate values at dataset edges or close to␣
↪nodata values
```

Details for options can be found in *gdal raster tpi*.

tri

```
* tri [OPTIONS]
---------------

Generate a Terrain Ruggedness Index (TRI) map

Options:
  -b, --band <BAND>        Input band (1-based index) (default: 1)
  --algorithm <ALGORITHM>  Algorithm to compute TRI. ALGORITHM=Riley|Wilson (default:␣
↪Riley)
  --no-edges               Do not try to interpolate values at dataset edges or close to␣
↪nodata values
```

Details for options can be found in *gdal raster tri*.

unscale

```
* unscale [OPTIONS]
-------------------

Convert scaled values of a raster dataset into unscaled values.

Options:
  --ot, --datatype, --output-data-type <OUTPUT-DATA-TYPE>  Output data type. OUTPUT-DATA-
↪TYPE=UInt8|Int8|UInt16|Int16|UInt32|Int32|UInt64|Int64|CInt16|CInt32|Float16|Float32|Float64|CFloat32
```

Details for options can be found in *gdal raster unscale*.

update

```
* update [OPTIONS] <OUTPUT>
---------------------------

Update the destination raster with the content of the input one.

Positional arguments:
  -o, --output <OUTPUT>                      Output raster dataset [required]

Options:
  --geometry <GEOMETRY>                      Clipping geometry (WKT or GeoJSON)
  --geometry-crs <GEOMETRY-CRS>              CRS of clipping geometry
  -r, --resampling <RESAMPLING>              Resampling method.␣
↪RESAMPLING=nearest|bilinear|cubic|cubicspline|lanczos|average|rms|mode|min|max|med|q1|q3|sum␣
↪(default: nearest)
  --no-update-overviews                      Do not update existing overviews

Advanced Options:
  --wo, --warp-option <NAME>=<VALUE>         Warping option(s) [may be repeated]
  --to, --transform-option <NAME>=<VALUE>    Transform option(s) [may be repeated]
  --et, --error-threshold <ERROR-THRESHOLD>  Error threshold
```

Details for options can be found in *gdal raster update*.

viewshed

```
* viewshed [OPTIONS]
--------------------

Compute the viewshed of a raster dataset.

Options:
  -p, --pos, --position <X,Y> or <X,Y,H>           Observer position [2..3 values]
  -z, --height <HEIGHT>                            Observer height
  --sd-filename <SD-FILENAME>                      Filename of standard-deviation raster
  --target-height <TARGET-HEIGHT>                  Height of the target above the DEM␣
↪surface in the height unit of the DEM. (default: 0)
  --mode <MODE>                                    Sets what information the output␣
↪contains.. MODE=normal|DEM|ground|cumulative (default: normal)
  --max-distance <MAX-DISTANCE>                    Maximum distance from observer to␣
↪compute visibility. It is also used to clamp the extent of the output raster.
  --min-distance <MIN-DISTANCE>                    Mask all cells less than this␣

```

Details for options can be found in *gdal raster viewshed*.

write

```
* write [OPTIONS] <OUTPUT>
--------------------------

Write a raster dataset.

Positional arguments:
  -o, --output <OUTPUT>                                Output raster dataset [required]

Options:
  -f, --of, --format, --output-format <OUTPUT-FORMAT>  Output format ("GDALG" allowed)
  --co, --creation-option <KEY>=<VALUE>                Creation option [may be repeated]
  --overwrite                                          Whether overwriting existing␣
↪output dataset is allowed
                                                       Mutually exclusive with --append
  --append                                             Append as a subdataset to␣
↪existing output
                                                       Mutually exclusive with --
↪overwrite
```

Details for options can be found in *gdal raster pipeline write*.

GDALG output (on-the-fly / streamed dataset)

A pipeline can be serialized as a JSON file using the `GDALG` output format. The resulting file can then be opened as a raster dataset using the *GDALG: GDAL Streamed Algorithm* driver, and apply the specified pipeline in a on-the-fly / streamed way.

The `command_line` member of the JSON file should nominally be the whole command line without the final `write` step, and is what is generated by `gdal raster pipeline ! .... ! write out.gdalg.json`.

```
{
    "type": "gdal_streamed_alg",
    "command_line": "gdal raster pipeline ! read in.tif ! reproject --output-
↪crs=EPSG:32632"
}
```

The final `write` step can be added but if so it must explicitly specify the `stream` output format and a non-significant output dataset name.

```
{
    "type": "gdal_streamed_alg",
    "command_line": "gdal raster pipeline ! read in.tif ! reproject --output-
↪crs=EPSG:32632 ! write --output-format=streamed streamed_dataset"
}
```

Substitutions

Added in version 3.12.

It is possible to use **`gdal pipeline`** to use a pipeline already serialized in a .gdal.json file, and customize its existing steps, typically changing an input filename, specifying an output filename, or adding/modifying arguments of steps.

See *Substitutions*.

Nested pipeline

Added in version 3.12.

It is possible to create "nested pipelines", i.e. pipelines inside pipelines.

A nested pipeline is delimited by square brackets (`[` and `]`) surrounded by a space character.

There are 2 kinds of nested pipelines:

- input nested pipelines: where the result dataset of the nested pipeline is used as the input dataset for an argument of the main pipeline.
- output nested pipelines: where the output of a step of the main pipeline is used as the input of the nested pipeline in a following step. Output nested pipelines can only be used with the `tee` step.

See *Nested pipeline*.

Return status code

The program returns status code 0 in case of success, and non-zero in case of error (non-blocking errors emitted as warnings are considered as a successful execution).

Examples

Example 1: Reproject a GeoTIFF file to CRS EPSG:32632 ("WGS 84 / UTM zone 32N") and adding a metadata item

```
$ gdal raster pipeline ! read in.tif ! reproject --output-crs=EPSG:32632 ! edit --
↪metadata AUTHOR=EvenR ! write out.tif --overwrite
```

Example 2: Serialize the command of a reprojection of a GeoTIFF file in a GDALG file, and later read it

```
$ gdal raster pipeline ! read in.tif ! reproject --output-crs=EPSG:32632 ! write in_epsg_
↪32632.gdalg.json --overwrite
$ gdal raster info in_epsg_32632.gdalg.json
```

Example 3: Mosaic on-the-fly several input files and tile that mosaic.

```
gdal raster pipeline ! mosaic input*.tif ! tile output_folder
```

Example 4: Reclassify GeoTIFF and render it as RGB image.

```
$ gdal raster pipeline ! read in.tif ! reclassify -m "[1,10]=1; [11,20]=2; [21,30]=3;␣
↪DEFAULT=NO_DATA" --ot=Byte ! color-map --color-map=color_map.txt --color-
↪selection=exact --add-alpha ! write -f WEBP rendered.webp
```

5.1.3.29 gdal raster pixel-info

Added in version 3.11.

Synopsis

```
Usage: gdal raster pixel-info [OPTIONS] <INPUT> [<column,line> or <X,Y>]

Return information on a pixel of a raster dataset.

Positional arguments:
  -i, --dataset, --input <INPUT>                      Input raster datasets [required]
  -p, --pos, --position <column,line> or <X,Y>        Pixel position [may be repeated]
                                                      Mutually exclusive with --
↪position-dataset

Common Options:
  -h, --help                                          Display help message and exit
  --json-usage                                        Display usage as JSON document␣
↪and exit
  --config <KEY>=<VALUE>                              Configuration option [may be␣
↪repeated]

Options:
  -f, --of, --format, --output-format <OUTPUT-FORMAT>  Output format (default is 'GeoJSON
```

↪Z component of GeoJSON geometry
  --include-field <INCLUDE-FIELD>                      Fields from coordinate dataset to␣
↪include in output (special values: ALL and NONE) (default: ALL) [may be repeated]

Advanced Options:
  --oo, --open-option <KEY>=<VALUE>                    Open options [may be repeated]␣
↪[not available in pipelines]
  --if, --input-format <INPUT-FORMAT>                  Input formats [may be repeated]␣
↪[not available in pipelines]
```

Description

gdal raster pixel-info provide a mechanism to query information about a pixel given its location in one of a variety of coordinate systems.

The following items will be reported (when known):

- Input coordinates
- Input coordinates converted to column, line
- Pixel value per selected band(s), with unscaled value
- For VRT files, which file(s) contribute to the pixel value (only for GeoJSON output)

There are 3 possible ways of providing input location(s):

- from input stream, with a "X Y" pair per line, potentially followed by other text.
- though the *--position* argument.
- through a GDAL vector dataset through the *--position-dataset* argument.

There are 2 possibilities of outputting pixel information:

- either on the output stream as CSV or GeoJSON (default to GeoJSON)

- or as a GDAL vector dataset whose name is specified with the `--output` argument.

Since GDAL 3.13, this algorithm can be part of a *gdal pipeline*. In that case, only reading coordinates from a GDAL vector dataset and outputting results to one is supported.

Added in version 3.13.

GDALG output (on-the-fly / streamed dataset)

This program supports serializing the command line as a JSON file using the `GDALG` output format. The resulting file can then be opened as a vector dataset using the *GDALG: GDAL Streamed Algorithm* driver, and apply the specified pipeline in a on-the-fly / streamed way.

> **Note**
>
> However this algorithm is not natively streaming compatible. Consequently a in-memory temporary dataset will be generated, which may cause significant processing time at opening.

The following options are available:

Program-Specific Options

-b <band>

Selects a band to query. Multiple bands can be listed. By default all bands are queried.

-f, --of, --format, --output-format <FORMAT>

Which vector output format to use.

When `--output` is not specified, `csv` or `geojson` are the only two supported choices, with `geojson` being the default. Otherwise, any GDAL-supported vector format with write capabilities is supported.

--position-dataset <COORDINATE-DATASET>

Added in version 3.13.

GDAL-compatible vector dataset from which input coordinates are read. If the input feature has a point geometry, its location is used to query the raster. For other geometry types, the centroid is used. To read all pixel values for non-point geometries, use *gdal raster zonal-stats*. By default, all attribute fields are copied to the output.

If the `--position-crs` argument is specified, the coordinates of the point are interpreted according to the value of that argument.

Otherwise, if the input vector layer has a CRS, coordinates are assumed to be expressed in it.

Otherwise, coordinates are assumed to be in the CRS raster dataset if it has a CRS.

Otherwise, coordinates are assumed to be expressed in the column,line raster space.

-l, --layer, --input-layer <INPUT-LAYER>

Added in version 3.13.

Input layer name of the dataset specified with `--position-dataset` to use.

-o, --output <OUTPUT>

Added in version 3.13.

Output vector dataset (created by algorithm)

--include-field <FIELD>

Added in version 3.13.

Name of the field(s) from *--position-dataset* to include into the output. By default, all fields are included (which corresponds to special value `ALL`). Special value `NONE` can be used to mean that no field from the position dataset must be included in the output.

--ovr, --overview <index>

Query the (overview_level)th overview (overview_level=0 is the 1st overview), instead of the base band. Note that the x,y location (if the coordinate system is pixel/line) must still be given with respect to the base band.

-p, --pos, --position <column,line> or <X,Y>

Required, if *--position-dataset* is not specified and no content is provided through the input stream.

This can be specified either as an option, a positional value after the dataset name, or when called from **gdal**, as (space separated) values provided on the standard input.

By default, when *--position-crs* is not specified, or set to `pixel`, this is a column, line tuple (possibly with fractional part). If *--position-crs* is set to `dataset`, this is a georeferenced coordinate expressed in the CRS of the dataset. If *--position-crs* is specified to a CRS definition, this is a georeferenced coordinate expressed in this CRS.

X means always longitude or easting, Y means always latitude or northing.

Several x,y tuples may be specified.

--position-crs pixel|dataset|<crs-def>

CRS of position, or one of two following special values:

- `pixel` means that the position is set as column, line (default)
- `dataset` means that the position is a georeferenced coordinate expressed in the CRS of the dataset.

--promote-pixel-value-to-z

Added in version 3.13.

Whether to set the pixel value as Z component of GeoJSON geometry. Only applies if a single band is selected, and for GeoJSON output format.

-r, --resampling nearest|bilinear|cubic|cubicspline

Select a sampling algorithm. The default is `nearest`.

The available methods are:

- `nearest` applies a nearest neighbour.
- `bilinear` applies a bilinear convolution kernel.
- `cubic` applies a cubic convolution kernel.
- `cubicspline` applies a B-Spline convolution kernel.

Standard Options

--oo, --open-option <NAME>=<VALUE>

Dataset open option (format specific).

May be repeated.

--if, --input-format <format>

Format/driver name to be attempted to open the input file(s). It is generally not necessary to specify it, but it can be used to skip automatic driver detection, when it fails to select the appropriate driver. This option can be repeated several times to specify several candidate drivers. Note that it does not force those drivers to open the dataset. In particular, some drivers have requirements on file extensions.

May be repeated.

--co, --creation-option <NAME>=<VALUE>

Many formats have one or more optional creation options that can be used to control particulars about the file created. For instance, the GeoTIFF driver supports creation options to control compression, and whether the file should be tiled.

May be repeated.

The creation options available vary by format driver, and some simple formats have no creation options at all. A list of options supported for a format can be listed with the *--formats* command line option but the documentation for the format is the definitive source of information on driver creation options. See *Raster drivers* format specific documentation for legal creation options for each format.

--lco, --layer-creation-option <NAME>=<VALUE>

Many formats have one or more optional layer creation options that can be used to control particulars about the layer created. For instance, the GeoPackage driver supports layer creation options to control the feature identifier or geometry column name, setting the identifier or description, etc.

May be repeated.

The layer creation options available vary by format driver, and some simple formats have no layer creation options at all. A list of options supported for a format can be listed with the *--formats* command line option but the documentation for the format is the definitive source of information on driver creation options. See *Vector drivers* format specific documentation for legal creation options for each format.

Note that layer creation options are different from dataset creation options.

--overwrite

Allow program to overwrite existing target file or dataset. Otherwise, by default, **gdal** errors out if the target file or dataset already exists.

Return status code

The program returns status code 0 in case of success, and non-zero in case of error (non-blocking errors emitted as warnings are considered as a successful execution).

Examples

Example 1: Reporting on pixel column=5, line=10 on the file byte.tif

```
$ gdal raster pixel-info byte.tif 5 10
{
  "type":"FeatureCollection",
  "crs":{
    "type":"name",
    "properties":{
      "name":"urn:ogc:def:crs:EPSG::26711"
    }
  },
  "features":[
```

(continues on next page)

(continued from previous page)

```
    {
      "type":"Feature",
      "properties":{
        "input_coordinate":[
          5.0,
          10.0
        ],
        "column":5.0,
        "line":10.0,
        "bands":[
          {
            "band_number":1,
            "raw_value":132,
            "unscaled_value":132.0
          }
        ]
      },
      "geometry":{
        "type":"Point",
        "coordinates":[
          441020.0,
          3750720.0
        ]
      }
    }
  ]
}
```

Example 2: Reporting on point at UTM 11N coordinates easting=441320 and northing=3750720 on the file byte.tif

```
$ gdal raster pixel-info --position-crs=dataset byte.tif 441320 3750720
{
  "type":"FeatureCollection",
  "crs":{
    "type":"name",
    "properties":{
      "name":"urn:ogc:def:crs:EPSG::26711"
    }
  },
  "features":[
    {
      "type":"Feature",
      "properties":{
        "input_coordinate":[

↪repeated] [not available in pipelines]
```

Description

gdal raster polygonize creates vector polygons for all connected regions of pixels in the raster sharing a common pixel value. Each polygon is created with an attribute indicating the pixel value of that polygon. Pixels that are set to the NoData value, or masked using an external mask band, are not included in processing.

The utility can create the output vector dataset if it does not already exist, otherwise it may append to an existing one.

The utility is based on the :*GDALPolygonize()* function which has additional details on the algorithm.

Since GDAL 3.12, this algorithm can be part of a *gdal pipeline*.

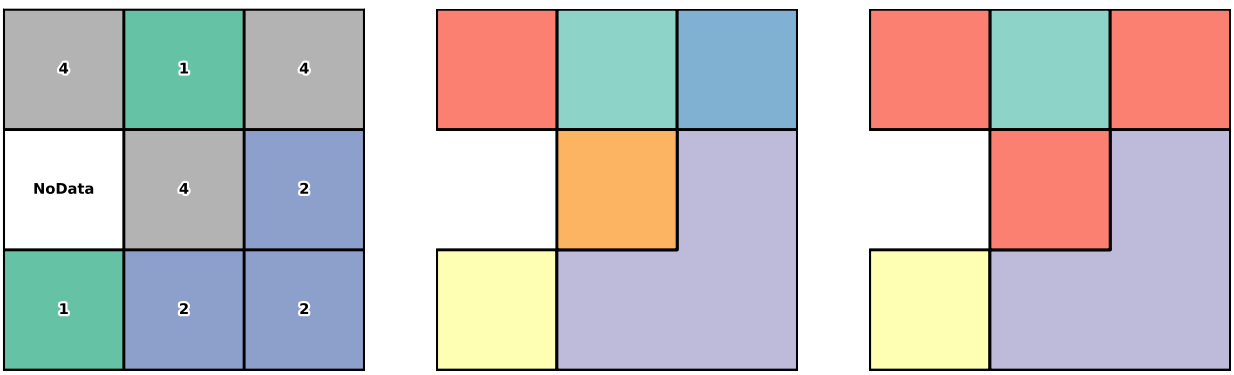

Fig. 2: Polygonization of a 3x3 raster input. The middle figure shows the default behavior, where separate polygons are created for pixel regions that are connected only to a diagonal neighbor. In the figure on the right, `--connect-diagonal-pixels` has been specified, and a single polygon has been created for pixels with value 4.

Added in version 3.12.

GDALG output (on-the-fly / streamed dataset)

This program supports serializing the command line as a JSON file using the `GDALG` output format. The resulting file can then be opened as a vector dataset using the *GDALG: GDAL Streamed Algorithm* driver, and apply the specified pipeline in a on-the-fly / streamed way.

> **Note**
>
> However this algorithm is not natively streaming compatible. Consequently a in-memory temporary dataset will be generated, which may cause significant processing time at opening.

Program-Specific Options

--attribute-name <ELEVATION-NAME>

The name of the field to create (defaults to "DN").

-b, --band <BAND>

Picks a particular band to polygonize. Defaults to band 1.

-c, --connect-diagonal-pixels

Consider diagonal pixels (pixels at the corners) as connected. The default behavior is to only consider pixels that are touching the edges as connected, which is the same as 4-connectivity. When this option is selected, the algorithm will also consider pixels at the corners as connected, which is the same as 8-connectivity.

--nln, --output-layer <OUTPUT-LAYER>

Provides a name for the output vector layer. Defaults to "polygonize".

Standard Options

--append

Whether appending features to existing layer(s) is allowed. This also creates the output dataset if it does not exist yet.

--co, --creation-option <NAME>=<VALUE>

Many formats have one or more optional creation options that can be used to control particulars about the file created. For instance, the GeoTIFF driver supports creation options to control compression, and whether the file should be tiled.

May be repeated.

The creation options available vary by format driver, and some simple formats have no creation options at all. A list of options supported for a format can be listed with the *--formats* command line option but the documentation for the format is the definitive source of information on driver creation options. See *Raster drivers* format specific documentation for legal creation options for each format.

--if, --input-format <format>

Format/driver name to be attempted to open the input file(s). It is generally not necessary to specify it, but it can be used to skip automatic driver detection, when it fails to select the appropriate driver. This option can be repeated several times to specify several candidate drivers. Note that it does not force those drivers to open the dataset. In particular, some drivers have requirements on file extensions.

May be repeated.

--lco, --layer-creation-option <NAME>=<VALUE>

Many formats have one or more optional layer creation options that can be used to control particulars about the layer created. For instance, the GeoPackage driver supports layer creation options to control the feature identifier or geometry column name, setting the identifier or description, etc.

May be repeated.

The layer creation options available vary by format driver, and some simple formats have no layer creation options at all. A list of options supported for a format can be listed with the *--formats* command line option but the documentation for the format is the definitive source of information on driver creation options. See *Vector drivers* format specific documentation for legal creation options for each format.

Note that layer creation options are different from dataset creation options.

-f, --of, --format, --output-format <OUTPUT-FORMAT>

Which output vector format to use. Allowed values may be given by `gdal --formats | grep vector | grep rw | sort`

--oo, --open-option <NAME>=<VALUE>

Dataset open option (format specific).

May be repeated.

--output-open-option, --output-oo <NAME>=<VALUE>

Added in version 3.12.

Dataset open option for output dataset (format specific).

May be repeated.

--overwrite

Allow program to overwrite existing target file or dataset. Otherwise, by default, **gdal** errors out if the target file or dataset already exists.

--overwrite-layer

Whether overwriting the existing output vector layer is allowed.

--update

Whether to open an existing output dataset in update mode.

Return status code

The program returns status code 0 in case of success, and non-zero in case of error (non-blocking errors emitted as warnings are considered as a successful execution).

Examples

Example 1: Create a shapefile with polygons for the connected regions of band 1 of the input GeoTIFF.

```
gdal raster polygonize input.tif polygonize.shp
```

5.1.3.31 gdal raster proximity

Added in version 3.12.

Synopsis

```
Usage: gdal raster proximity [OPTIONS] <INPUT> <OUTPUT>

Produces a raster proximity map.

Positional arguments:
  -i, --input <INPUT>                                       Input raster datasets␣
↪[required] [not available in pipelines]
  -o, --output <OUTPUT>                                     Output raster dataset␣
↪[required] [not available in pipelines]

Common Options:
  -h, --help                                                Display help message and exit
  --json-usage                                              Display usage as JSON␣

↪repeated] [not available in pipelines]
```

Description

gdal raster proximity generates a raster proximity map indicating the Cartesian distance from the center of each pixel to the center of the nearest pixel identified as a target pixel. Target pixels are those in the source raster for which the raster pixel value is in the set of target pixel values.

This subcommand is also available as a potential step of *gdal raster pipeline*

Added in version 3.12.

GDALG output (on-the-fly / streamed dataset)

This program supports serializing the command line as a JSON file using the `GDALG` output format. The resulting file can then be opened as a raster dataset using the *GDALG: GDAL Streamed Algorithm* driver, and apply the specified pipeline in a on-the-fly / streamed way.

> **Note**
>
> However this algorithm is not natively streaming compatible. Consequently a temporary dataset will be generated, which may cause significant processing time at opening.

Program-Specific Options

-b, --band <BAND>

Input band (1-based index)

--distance-units <pixel|geo>

Units for the distance. If *geo* is specified, the distance will be calculated in georeferenced units (meters or degrees) using the pixel size of the input raster. Otherwise, the distance is interpreted in pixels.

--fixed-value <FIXED-VALUE>

Define a fixed value to be written to output pixels that are within *--max-distance* from the target pixels, instead of the actual distance.

--max-distance <MAX-DISTANCE>

Maximum distance to search for a target pixel. The NoData value will be output if no target pixel is found within this distance. Distance is interpreted in pixels unless *--distance-units geo* is specified.

--nodata <NODATA>

Nodata value for the output raster. If not specified, the NoData value of the input band will be used. If the output band does not have a NoData value, then the value 65535 will be used for floating point output types and the maximum value that can be stored will be used for the integer output types.

--target-values <TARGET-VALUES>

A single value or a comma separated list of target pixel values in the source image to be considered target pixels. If not specified, all non-zero pixels will be considered target pixels.

Standard Options

--append

Append input raster as a new subdataset to an existing output file. Only works with drivers that support adding subdatasets such as *GTiff -- GeoTIFF File Format* and *GPKG -- GeoPackage raster* This also creates the output dataset if it does not exist yet.

--co, --creation-option <NAME>=<VALUE>

Many formats have one or more optional creation options that can be used to control particulars about the file created. For instance, the GeoTIFF driver supports creation options to control compression, and whether the file should be tiled.

May be repeated.

The creation options available vary by format driver, and some simple formats have no creation options at all. A list of options supported for a format can be listed with the *--formats* command line option but the documentation for the format is the definitive source of information on driver creation options. See *Raster drivers* format specific documentation for legal creation options for each format.

--if, --input-format <format>

Format/driver name to be attempted to open the input file(s). It is generally not necessary to specify it, but it can be used to skip automatic driver detection, when it fails to select the appropriate driver. This option can be repeated several times to specify several candidate drivers. Note that it does not force those drivers to open the dataset. In particular, some drivers have requirements on file extensions.

May be repeated.

--oo, --open-option <NAME>=<VALUE>

Dataset open option (format specific).

May be repeated.

-f, --of, --format, --output-format <OUTPUT-FORMAT>

Which output raster format to use. Allowed values may be given by `gdal --formats | grep raster | grep rw | sort`

--ot, --datatype, --output-data-type <OUTPUT-DATA-TYPE>

Output data type among `Byte`, `Int8`, `UInt16`, `Int16`, `UInt32`, `Int32`, `UInt64`, `Int64`, `CInt16`, `CInt32`, `Float32`, `Float64`, `CFloat32`, `CFloat64`.

--overwrite

Allow program to overwrite existing target file or dataset. Otherwise, by default, **gdal** errors out if the target file or dataset already exists.

Return status code

The program returns status code 0 in case of success, and non-zero in case of error (non-blocking errors emitted as warnings are considered as a successful execution).

Examples

Example 1

title

Proximity map of a raster with max distance of 3 pixels

```
$ gdal raster proximity --max-distance 3  input.tif output.tif
```

Example 2

title

Proximity map of a two bands raster with different target values for each band using a pipeline stack

```
$ gdal raster pipeline stack \
       [ read input.tif ! proximity -b 1 --target-values 1,2,3 ] \
       [ read input.tif ! proximity -b 2 --target-values 4,5,6 ] ! \
       write output.tif
```

5.1.3.32 gdal raster pipeline read

Added in version 3.11.

Description

The `read` operation is for use in a *gdal pipeline* only, and reads a single input raster dataset. This is the first step of a pipeline.

Synopsis

```
* read [OPTIONS] <INPUT>
------------------------

Read a raster dataset.

Positional arguments:
  -i, --input <INPUT>                  Input raster datasets [required]

Advanced Options:
  --if, --input-format <INPUT-FORMAT>  Input formats [may be repeated]
  --oo, --open-option <KEY>=<VALUE>    Open options [may be repeated]
```

Standard Options

--if, --input-format <format>

Format/driver name to be attempted to open the input file(s). It is generally not necessary to specify it, but it can be used to skip automatic driver detection, when it fails to select the appropriate driver. This option can be repeated several times to specify several candidate drivers. Note that it does not force those drivers to open the dataset. In particular, some drivers have requirements on file extensions.

May be repeated.

--oo, --open-option <NAME>=<VALUE>

Dataset open option (format specific).

May be repeated.

Examples

Example 1: Read a GeoTIFF file

```
$ gdal raster pipeline read input.tif ! ... [other commands here] ...
```

5.1.3.33 gdal raster reclassify

Added in version 3.11.

Synopsis

```
Usage: gdal raster reclassify [OPTIONS] <INPUT> <OUTPUT>

Reclassify values in a raster dataset

Positional arguments:
  -i, --input <INPUT>                                    Input raster datasets␣
↪[required] [not available in pipelines]

↪repeated] [not available in pipelines]
```

Description

gdal raster reclassify reclassifies values in an input dataset. A file (or string) specifies the mapping of input pixel values or ranges to output files.

Ranges of values can be specified using brackets:

Notation	Meaning
[a,b]	Closed interval, includes both a and b
[a,b)	Left-closed, right-open, includes a but excludes b
(a,b]	Left-open, right-closed, excludes a but includes b
(a,b)	Open interval, excludes both a and b

An example file is shown below.

```
# remap land cover types
0       = 10      # land
[2,4]   = 20      # freshwater
1       = 40      # ocean
```

(continues on next page)

(continued from previous page)

```
(4,6]    = 50       # forest (excludes 4, includes 5 and 6)
NO_DATA = NO_DATA # leave NoData pixels unmodified
```

The # character indicates a comment that is ignored by the parser but can make the file easier to read.) In this case:

- input values of 0 will be output as 10
- input values between 2 and 4 (inclusive) will be output as 20
- input values of 1 will be output as 40
- input values between 5 and 6 will be output as 50 (4 is excluded)
- NoData values will be preserved as NoData

The presence of any other values in the input will cause an error. If this is not desired, the input range `DEFAULT` can be used to specify an output value for pixels not covered by any other input range. These pixels may be converted unto NoData (`DEFAULT = NO_DATA`), some other constant value (e.g., `DEFAULT = 50`), or left unmodified (`DEFAULT = PASS_THROUGH`).

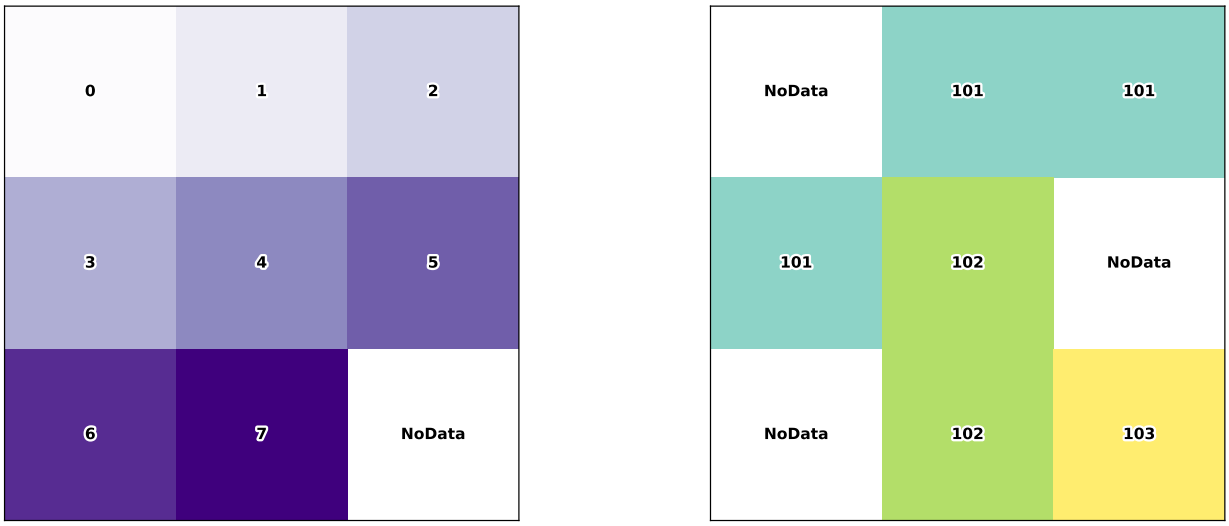

Fig. 3: Raster dataset before (left) and after (right) reclassification with **`gdal raster reclassify --mapping "[1,3]= 101; [4, 5)= 102; 7=102; NO_DATA=103; DEFAULT=NO_DATA"`**.

> **Note**
>
> **`gdal raster reclassify`** supports writing to VRT format; however, VRT files generated in this way can only be opened using GDAL 3.11 or greater.

GDALG output (on-the-fly / streamed dataset)

This program supports serializing the command line as a JSON file using the `GDALG` output format. The resulting file can then be opened as a raster dataset using the *GDALG: GDAL Streamed Algorithm* driver, and apply the specified pipeline in a on-the-fly / streamed way.

Program-Specific Options

-m, --mapping <MAPPING>

A definition of mappings between input and output pixel values, as described above. The mappings may either be provided as text (with each entry separate by a semicolon), or they may be read from a file using `@filename.txt`.

Standard Options

--append

Append input raster as a new subdataset to an existing output file. Only works with drivers that support adding subdatasets such as *GTiff -- GeoTIFF File Format* and *GPKG -- GeoPackage raster* This also creates the output dataset if it does not exist yet.

--co, --creation-option <NAME>=<VALUE>

Many formats have one or more optional creation options that can be used to control particulars about the file created. For instance, the GeoTIFF driver supports creation options to control compression, and whether the file should be tiled.

May be repeated.

The creation options available vary by format driver, and some simple formats have no creation options at all. A list of options supported for a format can be listed with the *--formats* command line option but the documentation for the format is the definitive source of information on driver creation options. See *Raster drivers* format specific documentation for legal creation options for each format.

--if, --input-format <format>

Format/driver name to be attempted to open the input file(s). It is generally not necessary to specify it, but it can be used to skip automatic driver detection, when it fails to select the appropriate driver. This option can be repeated several times to specify several candidate drivers. Note that it does not force those drivers to open the dataset. In particular, some drivers have requirements on file extensions.

May be repeated.

--oo, --open-option <NAME>=<VALUE>

Dataset open option (format specific).

May be repeated.

-f, --of, --format, --output-format <OUTPUT-FORMAT>

Which output raster format to use. Allowed values may be given by `gdal --formats | grep raster | grep rw | sort`

--ot, --datatype, --output-data-type <OUTPUT-DATA-TYPE>

Output data type among `Byte`, `Int8`, `UInt16`, `Int16`, `UInt32`, `Int32`, `UInt64`, `Int64`, `CInt16`, `CInt32`, `Float32`, `Float64`, `CFloat32`, `CFloat64`.

--overwrite

Allow program to overwrite existing target file or dataset. Otherwise, by default, **gdal** errors out if the target file or dataset already exists.

Return status code

The program returns status code 0 in case of success, and non-zero in case of error (non-blocking errors emitted as warnings are considered as a successful execution).

Examples

Example 1

```
$ gdal raster reclassify -m "0=10; [2,4]=20; 1=40" -i wbm.tif -o typ.tif
```

5.1.3.34 gdal raster reproject

Added in version 3.11.

Synopsis

```
Usage: gdal raster reproject [OPTIONS] <INPUT> <OUTPUT>

Reproject a raster dataset.

Positional arguments:
  -i, --input <INPUT>                                    Input raster datasets [required]␣

  --et, --error-threshold <ERROR-THRESHOLD>              Error threshold
```

Description

gdal raster reproject can be used to reproject a raster dataset. The program can reproject to any supported projection.

First, **gdal raster reproject** must determine the extent and resolution of the output, if these have not been specified using *--bbox* and *--resolution*. These are determined by transforming a sample of points from the source CRS to the destination CRS. Details of the procedure can be found in the documentation for *GDALSuggestedWarpOutput()*. If multiple inputs are provided to **gdal raster reproject**, the output extent will be calculated to cover all of them, at a resolution consistent with the highest-resolution input.

Once the dimensions of the output image have been determined, **gdal raster reproject** divides the output image into chunks that can be processed independently. **gdal raster reproject** then iterates over scanlines in these chunks, and for each output pixel determines a rectangular region of source pixels that contribute to the value of the output pixel. The dimensions of this rectangular region are typically determined by estimating the relative scales of the source and destination raster, but can be manually specified (see documentation of the `XSCALE` parameter in *GDALWarpOptions::papszWarpOptions*). Because the source region is a simple rectangle, it is not possible for an output pixel to be associated with source pixels from both sides of the antimeridian or pole (when transforming from geographic coordinates).

The rectangular region of source pixels is then provided to a function that performs the resampling algorithm selected with *--resampling*. Depending on the resampling algorithm and relative scales of the source and destination rasters, source pixels may be weighted either according to the approximate fraction of the source pixel that is covered by the destination pixel (e.g., "mean" and "sum" resampling), or by horizontal and vertical Cartesian distances between the center of the source pixel and the center of the target pixel (e.g., bilinear or cubic spline resampling). In the latter case, the relative weight of an individual source pixel is determined by the product of the weights determined for its row and

column; the diagonal Cartesian distance is not calculated.

This subcommand is also available as a potential step of *gdal raster pipeline*

Program-Specific Options

--add-alpha

Create an output alpha band to identify nodata (unset/transparent) pixels. Value 0 is used for fully transparent pixels. The maximum value for the alpha band, for fully opaque pixels, depends on the data type and the presence of the NBITS band metadata item. If it is present, the maximum value is 2^NBITS-1. Otherwise, if NBITS is not set and the alpha band is of type UInt16 (resp. Int16), 65535 (resp. 32767) is used. Otherwise, 255 is used. The maximum value can also be overridden with `--wo DST_ALPHA_MAX=<value>`.

--bbox `<xmin>,<ymin>,<xmax>,<ymax>`

Set georeferenced extents of output file to be created (in target SRS by default, or in the SRS specified with *--bbox-crs*)

--bbox-crs `<BBOX-CRS>`

Specifies the SRS in which to interpret the coordinates given with *--bbox*.

The coordinate reference systems that can be passed are anything supported by the OGRSpatialReference.SetFromUserInput() call, which includes EPSG Projected, Geographic or Compound CRS (i.e. EPSG:4296), a well known text (WKT) CRS definition, PROJ.4 declarations, or the name of a .prj file containing a WKT CRS definition.

If the SRS has an explicit vertical datum that points to a geoid grid, and the input dataset is a single band dataset, a vertical correction will be applied to the values of the dataset.

This must not be confused with *--output-crs* which is the target SRS of the output dataset. *--bbox-crs* is a convenience e.g. when knowing the output coordinates in a geodetic long/lat SRS, but still wanting a result in a projected coordinate system.

--like `<DATASET>`

Name of GDAL input dataset that serves as a template for default values of options *--size*, *--resolution* *--output-crs* and *--bbox* Note that the pixel values will *not* be copied, and that spatial registration of the template dataset through mechanisms such as GCP, RPC or geolocation array is ignored.

--et, --error-threshold `<ERROR-THRESHOLD>`

Error threshold for transformation approximation, expressed as a number of source pixels. Defaults to 0.125 pixels unless the `RPC_DEM` transformer option is specified, in which case an exact transformer, i.e. `--error-threshold=0`, will be used.

-j, --num-threads `<value>`

Added in version 3.12.

Number of jobs to run at once. Default: number of CPUs detected.

--input-crs, -s `<INPUT-CRS>`

Set input spatial reference. If not specified the SRS found in the input dataset will be used.

The coordinate reference systems that can be passed are anything supported by the OGRSpatialReference.SetFromUserInput() call, which includes EPSG Projected, Geographic or Compound CRS (i.e. EPSG:4296), a well known text (WKT) CRS definition, PROJ.4 declarations, or the name of a .prj file containing a WKT CRS definition.

If the SRS has an explicit vertical datum that points to a geoid grid, and the input dataset is a single band dataset, a vertical correction will be applied to the values of the dataset.

--input-nodata <NODATA>

Set nodata masking values for input bands (different values can be supplied for each band). If more than one value is supplied all values should be quoted to keep them together as a single operating system argument. Masked values will not be used in interpolation (details given in *Nodata / source validity mask handling*)

Use a value of `None` to ignore intrinsic nodata settings on the source dataset.

When this option is set to a non-`None` value, it causes the `UNIFIED_SRC_NODATA` warping option (see *`GDALWarpOptions::papszWarpOptions`*) to be set to `YES`, if it is not explicitly set.

If `--input-nodata` is not explicitly set, but the source dataset has nodata values, they will be taken into account, with `UNIFIED_SRC_NODATA` at `PARTIAL` by default.

--output-crs, -d, <OUTPUT-CRS>

Set output spatial reference. If not specified the SRS found in the input dataset will be used.

The coordinate reference systems that can be passed are anything supported by the OGRSpatialReference.SetFromUserInput() call, which includes EPSG Projected, Geographic or Compound CRS (i.e. EPSG:4296), a well known text (WKT) CRS definition, PROJ.4 declarations, or the name of a .prj file containing a WKT CRS definition.

If the SRS has an explicit vertical datum that points to a geoid grid, and the input dataset is a single band dataset, a vertical correction will be applied to the values of the dataset.

--output-nodata <NODATA>

Set nodata values for output bands (different values can be supplied for each band). If more than one value is supplied all values should be quoted to keep them together as a single operating system argument. New files will be initialized to this value and if possible the nodata value will be recorded in the output file. Use a value of `None` to ensure that nodata is not defined. If this argument is not used then nodata values will be copied from the source dataset. Note that a number of output formats, including GeoTIFF, do not support different per-band nodata values, but a single one for all bands.

-r, --resampling <RESAMPLING>

Resampling method to use. Available methods are:

`nearest`: nearest neighbour resampling (default, fastest algorithm, worst interpolation quality).

`bilinear`: bilinear resampling.

`cubic`: cubic resampling.

`cubicspline`: cubic spline resampling.

`lanczos`: Lanczos windowed sinc resampling.

`average`: average resampling, computes the weighted average of all non-NODATA contributing pixels.

`rms` root mean square / quadratic mean of all non-NODATA contributing pixels

`mode`: mode resampling, selects the value which appears most often of all the sampled points. In the case of ties, the first value identified as the mode will be selected.

`max`: maximum resampling, selects the maximum value from all non-NODATA contributing pixels.

`min`: minimum resampling, selects the minimum value from all non-NODATA contributing pixels.

`med`: median resampling, selects the median value of all non-NODATA contributing pixels.

`q1`: first quartile resampling, selects the first quartile value of all non-NODATA contributing pixels.

`q3`: third quartile resampling, selects the third quartile value of all non-NODATA contributing pixels.

`sum`: compute the weighted sum of all non-NODATA contributing pixels

> **Note**
>
> When downsampling is performed (use of *--resolution* or *--size*), existing overviews (either internal/implicit or external ones) on the source image will be used by default by selecting the closest overview to the desired output resolution. The resampling method used to create those overviews is generally not the one you specify through the *-r* option.

--resolution <xres>,<yres>

Set output file resolution (in target georeferenced units).

If not specified (or not deduced from *--size*), the program will, in the general case, generate an output raster with xres=yres.

If neither *--resolution* nor *--size* are specified, that no reprojection is involved (including taking into account geolocation arrays or RPC), the resolution of the source file(s) will be preserved (in previous version, an output raster with xres=yres was always generated).

Mutually exclusive with *--size*.

--size <width>,<height>

Set output file size in pixels and lines. If width or height is set to 0, the other dimension will be guessed from the computed resolution.

Mutually exclusive with *--resolution*.

--target-aligned-pixels

Align the coordinates of the extent of the output file to the values of the *--resolution*, such that the aligned extent includes the minimum extent (edges lines/columns that are detected as blank, before actual warping, will be removed). Alignment means that xmin / resx, ymin / resy, xmax / resx and ymax / resy are integer values.

--to, --transform-option <NAME>=<VALUE>

Set a transformer option suitable to pass to *GDALCreateGenImgProjTransformer2()*. See *GDALCreateRPCTransformerV2()* for RPC specific options.

To match the gdalwarp -rpc option, use --to METHOD=RPC

--wo, --warp-option <NAME>=<VALUE>

Set a warp option. The *GDALWarpOptions::papszWarpOptions* docs show all options. Multiple options may be listed.

Standard Options

--append

Append input raster as a new subdataset to an existing output file. Only works with drivers that support adding subdatasets such as *GTiff -- GeoTIFF File Format* and *GPKG -- GeoPackage raster* This also creates the output dataset if it does not exist yet.

--co, --creation-option <NAME>=<VALUE>

Many formats have one or more optional creation options that can be used to control particulars about the file created. For instance, the GeoTIFF driver supports creation options to control compression, and whether the file should be tiled.

May be repeated.

The creation options available vary by format driver, and some simple formats have no creation options at all. A list of options supported for a format can be listed with the *--formats* command line option but the documentation for the format is the definitive source of information on driver creation options. See *Raster drivers* format specific documentation for legal creation options for each format.

--if, --input-format <format>

Format/driver name to be attempted to open the input file(s). It is generally not necessary to specify it, but it can be used to skip automatic driver detection, when it fails to select the appropriate driver. This option can be repeated several times to specify several candidate drivers. Note that it does not force those drivers to open the dataset. In particular, some drivers have requirements on file extensions.

May be repeated.

--oo, --open-option <NAME>=<VALUE>

Dataset open option (format specific).

May be repeated.

-f, --of, --format, --output-format <OUTPUT-FORMAT>

Which output raster format to use. Allowed values may be given by `gdal --formats | grep raster | grep rw | sort`

--overwrite

Allow program to overwrite existing target file or dataset. Otherwise, by default, **gdal** errors out if the target file or dataset already exists.

-q, --quiet

Suppress progress bar and some warning messages.

Nodata / source validity mask handling

Invalid values in source pixels, either identified through a nodata value metadata set on the source band, a mask band, an alpha band (for an alpha band, a value of 0 means invalid. Other values are used for blending values) or the use of *--input-nodata* will not be used in interpolation. The details of how it is taken into account depends on the resampling kernel:

- for nearest resampling, for each target pixel, the coordinate of its center is projected back to source coordinates and the source pixel containing that coordinate is identified. If this source pixel is invalid, the target pixel is considered as nodata.
- for bilinear, cubic, cubicspline and lanczos, for each target pixel, the coordinate of its center is projected back to source coordinates and a corresponding source pixel is identified. If this source pixel is invalid, the target pixel is considered as nodata (in this case, valid pixels within the kernel radius would not be considered). Given that those resampling kernels have a non-null kernel radius, this source pixel is just one among other several source pixels, and it might be possible that there are invalid values in those other contributing source pixels. The weights used to take into account those invalid values will be set to zero to ignore them.
- for the other resampling methods, source pixels contributing to the target pixel are ignored if invalid. Only the valid ones are taken into account. If there are none, the target pixel is considered as nodata.

Approximate transformation

By default **gdal raster reproject** uses a linear approximator for the transformations with a permitted error of 0.125 pixels in the source dataset. For each processing chunk, the approximator precisely transforms three points per output scanline (the start, middle, and end) from a row and column in the output dataset to a row and column in the source dataset. It then compares a linear approximation of the center point coordinates to the precisely transformed value. If the sum of the horizontal and vertical errors is less than the error threshold then the remaining source points are approximated using linear interpolation between the start and middle point, and between the middle and end point. If the error exceeds the threshold, the scanline is split into two sections and the approximator is recursively applied to each section until the error is less than the threshold or all points have been exactly computed.

Note that a processing chunk does not necessarily correspond to a whole destination scanline. If the output dataset is tiled, its shape will typically be one or several tiles. The `OPTIMIZE_SIZE` warping option can also influence the shape

of the processing chunk. Consequently, for a single (non-zero) value of the error threshold, the linear approximation might result in slightly different values in coordinate transformation, but all of them within the permitted error.

The error threshold (in source dataset pixels) can be controlled with the `--error-threshold` switch. If you want to compare a true pixel-by-pixel reprojection use `--error-threshold=0` which disables this approximator entirely.

Frequently Asked Questions

Q1. Why does the quality of the output looks so bad (no anti-aliasing)?

Did you specify a resampling method, with `--resampling`, other than the default nearest neighbour?

Q2. Why do I get slightly different results whether the output dataset is tiled or not?

This is related to the fact that an approximate coordinate transformation is used by default to speed-up computation. If you want to get the same results whether the output is tiled or not, set `--error-threshold` to zero. Note, however, that this will only work for relatively small images; other factors can still result in different result. See following question (Q3).

Q3. Why do I observe artifacts, that look like resolution changes and are aligned with rectangular areas of the output raster, when warping sufficiently large rasters, particularly in areas where the reprojection involves significant deformation and only with non-nearest resampling ?

The warping engine operates on rectangular areas of the output dataset (generally aligned with tile boundaries for a compressed tile dataset).

During reprojection, a single source pixel does not generally correspond to a single output pixel. The resampling method must therefore properly account for this and compute a ratio between the number of source and target pixels in the horizontal (X) and vertical (Y) directions. These ratios are computed per warping chunk. This maximizes the local quality of the warping but has the downside of creating visual discontinuities between warping chunks.

If you favor a seamless result, you may manually specify the XSCALE and YSCALE warping options with `--wo`. The XSCALE (resp. YSCALE) value is the ratio expressing the resampling factor, i.e. the number of destination pixels per source pixel, along the horizontal (resp. vertical) axis. It equals to one for no resampling, is below one for downsampling, and above one for upsampling.

GDALG output (on-the-fly / streamed dataset)

This program supports serializing the command line as a JSON file using the `GDALG` output format. The resulting file can then be opened as a raster dataset using the *GDALG: GDAL Streamed Algorithm* driver, and apply the specified pipeline in a on-the-fly / streamed way.

Return status code

The program returns status code 0 in case of success, and non-zero in case of error (non-blocking errors emitted as warnings are considered as a successful execution).

Examples

Example 1: Reproject a GeoTIFF file to CRS EPSG:32632 ("WGS 84 / UTM zone 32N")

```
$ gdal raster reproject --output-crs=EPSG:32632 in.tif out.tif --overwrite
```

Example 2: Converting a raster that uses an embedded CRS without a known identifier

In this example, the input file has an embedded CRS defined in WKT2 but without an associated identifier, and it will be reprojected to the known ESRI:54052 CRS identifier.

Using "PROFILE=BASELINE" creates a PAM file that stores the CRS using the ESRI:54052 identifier, instead of embedding CRS information in GeoTIFF metadata tags. See *GTiff* PROFILE.

```
$ gdal raster reproject --creation-option "PROFILE=BASELINE" --output-crs=ESRI:54052␣
↪input.tif output.tif --overwrite
```

5.1.3.35 gdal raster resize

Added in version 3.11.

Synopsis

```
Usage: gdal raster resize [OPTIONS] <INPUT> <OUTPUT>

Resize a raster dataset without changing the georeferenced extents.

Positional arguments:
  -i, --input <INPUT>                                    Input raster datasets [required]␣
↪[not available in pipelines]
  -o, --output <OUTPUT>                                  Output raster dataset [required]␣
↪[not available in pipelines]

Common Options:
  -h, --help                                             Display help message and exit
  --json-usage                                           Display usage as JSON document␣
↪and exit
  --config <KEY>=<VALUE>                                 Configuration option [may be␣

```

Description

gdal raster resize can be used to resize a raster dataset without changing the georeferenced extents.

This subcommand is also available as a potential step of *gdal raster pipeline*

GDALG output (on-the-fly / streamed dataset)

This program supports serializing the command line as a JSON file using the GDALG output format. The resulting file can then be opened as a raster dataset using the *GDALG: GDAL Streamed Algorithm* driver, and apply the specified pipeline in a on-the-fly / streamed way.

Program-Specific Options

-r, --resampling <RESAMPLING>

Resampling method to use. Available methods are:

nearest: nearest neighbour resampling (default, fastest algorithm, worst interpolation quality).

bilinear: bilinear resampling.

cubic: cubic resampling.

cubicspline: cubic spline resampling.

lanczos: Lanczos windowed sinc resampling.

average: average resampling, computes the weighted average of all non-NODATA contributing pixels.

--resolution <xres>,<yres>

Added in version 3.12.

Set output file resolution (in target georeferenced units).

Mutually exclusive with *--size*.

--size <width[%]>,<height[%]>

Set output raster width and height, expressed in pixels, or percentage if using the % suffix. If the width or the height is set to 0, the other dimension will be guessed from the computed resolution.

Mutually exclusive with *--resolution*.

Standard Options

--append

Append input raster as a new subdataset to an existing output file. Only works with drivers that support adding subdatasets such as *GTiff -- GeoTIFF File Format* and *GPKG -- GeoPackage raster* This also creates the output dataset if it does not exist yet.

--co, --creation-option <NAME>=<VALUE>

Many formats have one or more optional creation options that can be used to control particulars about the file created. For instance, the GeoTIFF driver supports creation options to control compression, and whether the file should be tiled.

May be repeated.

The creation options available vary by format driver, and some simple formats have no creation options at all. A list of options supported for a format can be listed with the *--formats* command line option but the documentation for the format is the definitive source of information on driver creation options. See *Raster drivers* format specific documentation for legal creation options for each format.

--if, --input-format <format>

Format/driver name to be attempted to open the input file(s). It is generally not necessary to specify it, but it can be used to skip automatic driver detection, when it fails to select the appropriate driver. This option can be repeated several times to specify several candidate drivers. Note that it does not force those drivers to open the dataset. In particular, some drivers have requirements on file extensions.

May be repeated.

--oo, --open-option <NAME>=<VALUE>

Dataset open option (format specific).

May be repeated.

-f, --of, --format, --output-format <OUTPUT-FORMAT>

Which output raster format to use. Allowed values may be given by `gdal --formats | grep raster | grep rw | sort`

--overwrite

Allow program to overwrite existing target file or dataset. Otherwise, by default, **gdal** errors out if the target file or dataset already exists.

Return status code

The program returns status code 0 in case of success, and non-zero in case of error (non-blocking errors emitted as warnings are considered as a successful execution).

Examples

Example 1: Resize a dataset to 1000 columns and 500 lines using cubic resampling

```
$ gdal raster resize --size=1000,500 -r cubic in.tif out.tif --overwrite
```

Example 2: Resize a dataset to half size using cubic resampling

```
$ gdal raster resize --size=50%,50% -r cubic in.tif out.tif --overwrite
```

5.1.3.36 gdal raster rgb-to-palette

Added in version 3.12.

Synopsis

```
Usage: gdal raster rgb-to-palette [OPTIONS] <INPUT> <OUTPUT>

Convert a RGB image into a pseudo-color / paletted image.

Positional arguments:
  -i, --input <INPUT>                                    Input raster datasets [required]␣
↪[not available in pipelines]
  -o, --output <OUTPUT>                                  Output raster dataset [required]␣
↪[not available in pipelines]

Common Options:
  -h, --help                                             Display help message and exit
  --json-usage                                           Display usage as JSON document␣
↪and exit
  --config <KEY>=<VALUE>                                 Configuration option [may be␣
↪repeated]
  -q, --quiet                                            Quiet mode (no progress bar or␣
↪warning message) [not available in pipelines]

Options:
  -f, --of, --format, --output-format <OUTPUT-FORMAT>  Output format ("GDALG" allowed)␣
↪[not available in pipelines]
  --co, --creation-option <KEY>=<VALUE>                  Creation option [may be repeated]␣

↪output dataset is allowed [not available in pipelines]
                                                         Mutually exclusive with --append
  --append                                               Append as a subdataset to␣
↪existing output [not available in pipelines]
                                                         Mutually exclusive with --
↪overwrite
  --color-count <COLOR-COUNT>                            Select the number of colors in␣
↪the generated color table (default: 256)
  --color-map <COLOR-MAP>                                Color map filename
  --output-nodata <OUTPUT-NODATA>                        Output nodata value
  --no-dither                                            Disable Floyd-Steinberg dithering
  --bit-depth <BIT-DEPTH>                                Bit depth of color palette␣
↪component (8 bit causes longer computation time). BIT-DEPTH=5|8 (default: 5)

Advanced Options:
  --if, --input-format <INPUT-FORMAT>                    Input formats [may be repeated]␣
↪[not available in pipelines]
  --oo, --open-option <KEY>=<VALUE>                      Open options [may be repeated]␣
↪[not available in pipelines]
```

Description

gdal raster rgb-to-palette computes an optimal pseudo-color table for a given RGB image using a median cut algorithm on a downsampled RGB histogram, unless a color table is provided with the *--color-map* option. Then it converts the image into a pseudo-colored image using the color table. This conversion utilizes by default Floyd-Steinberg dithering (error diffusion) to maximize output image visual quality.

This subcommand is also available as a potential step of *gdal raster pipeline*

GDALG output (on-the-fly / streamed dataset)

This program supports serializing the command line as a JSON file using the `GDALG` output format. The resulting file can then be opened as a raster dataset using the *GDALG: GDAL Streamed Algorithm* driver, and apply the specified pipeline in a on-the-fly / streamed way.

> **Note**
>
> However this algorithm is not natively streaming compatible. Consequently a temporary dataset will be generated, which may cause significant processing time at opening.

Program-Specific Options

--color-count <COLOR-COUNT>

Select the number of colors in the generated color table. Defaults to 256. Must be between 2 and 256.

--color-map <FILENAME>

Extract the color table from <FILENAME> instead of computing it. Can be used to have a consistent color table for multiple files. The <FILENAME> must be either a raster file in a GDAL supported format with a palette or a color file in a supported format (.txt, QGIS .qml, QGIS .qlr).

--output-nodata <VALUE>

Added in version 3.13.

Specifies the output nodata value, that will be used for input pixels at the source nodata value or that are transparent due to a mask band, such as an alpha band. The destination nodata value must be between 0 and 255. If there is a source nodata value or a dataset-wide mask band is attached to the source bands, and *--output-nodata* is not specified, it defaults to 0.

--no-dither

Added in version 3.13.

Disable Floyd-Steinberg dithering (error diffusion). This may be useful to improve the compression rate by avoiding the "noise" added by error diffusion.

--bit-depth 5|8

Added in version 3.13.

Bit depth of each of the output color table R, G, B component. The default value is 5, which means that each of the component is limited to 32 = 2 ^ 5 values. Setting bit depth to 8 increases the fidelity of the output color table at the expense of longer computation time.

Standard Options

--co, --creation-option <NAME>=<VALUE>

Many formats have one or more optional creation options that can be used to control particulars about the file created. For instance, the GeoTIFF driver supports creation options to control compression, and whether the file should be tiled.

May be repeated.

The creation options available vary by format driver, and some simple formats have no creation options at all. A list of options supported for a format can be listed with the *--formats* command line option but the documentation

for the format is the definitive source of information on driver creation options. See *Raster drivers* format specific documentation for legal creation options for each format.

-f, --of, --format, --output-format <OUTPUT-FORMAT>

Which output raster format to use. Allowed values may be given by `gdal --formats | grep raster | grep rw | sort`

--overwrite

Allow program to overwrite existing target file or dataset. Otherwise, by default, **gdal** errors out if the target file or dataset already exists.

Return status code

The program returns status code 0 in case of success, and non-zero in case of error (non-blocking errors emitted as warnings are considered as a successful execution).

Examples

Example 1

Convert a TIFF file into a paletted PNG image

```
$ gdal raster rgb-to-palette input.tif output.png
```

5.1.3.37 gdal raster roughness

Added in version 3.11.

Synopsis

```

Description

gdal raster roughness generates a single-band raster with values computed from the elevation. Roughness is the largest inter-cell difference of a central pixel and its surrounding cell, as defined in Wilson et al. (2007, Marine Geodesy 30:3-35).

This subcommand is also available as a potential step of *gdal raster pipeline*

The roughness value -9999 is used as the nodata value.

A nodata value in the target dataset will also be emitted if at least one pixel set to the nodata value is found in the 3x3 window centered around each source pixel. By default, the algorithm will compute values at image edges or if a nodata value is found in the 3x3 window, by interpolating missing values, unless `--no-edges` is specified, in which case a 1-pixel border around the image will be set with the nodata value.

GDALG output (on-the-fly / streamed dataset)

This program supports serializing the command line as a JSON file using the `GDALG` output format. The resulting file can then be opened as a raster dataset using the *GDALG: GDAL Streamed Algorithm* driver, and apply the specified pipeline in a on-the-fly / streamed way.

Program-Specific Options

-b, --band <BAND>

Index (starting at 1) of the band to which the roughness must be computed.

--no-edges

Do not try to interpolate values at dataset edges or close to nodata values

Standard Options

--append

Append input raster as a new subdataset to an existing output file. Only works with drivers that support adding subdatasets such as *GTiff -- GeoTIFF File Format* and *GPKG -- GeoPackage raster* This also creates the output dataset if it does not exist yet.

--co, --creation-option <NAME>=<VALUE>

Many formats have one or more optional creation options that can be used to control particulars about the file created. For instance, the GeoTIFF driver supports creation options to control compression, and whether the file should be tiled.

May be repeated.

The creation options available vary by format driver, and some simple formats have no creation options at all. A list of options supported for a format can be listed with the *--formats* command line option but the documentation for the format is the definitive source of information on driver creation options. See *Raster drivers* format specific documentation for legal creation options for each format.

--if, --input-format <format>

Format/driver name to be attempted to open the input file(s). It is generally not necessary to specify it, but it can be used to skip automatic driver detection, when it fails to select the appropriate driver. This option can be repeated several times to specify several candidate drivers. Note that it does not force those drivers to open the dataset. In particular, some drivers have requirements on file extensions.

May be repeated.

--oo, --open-option <NAME>=<VALUE>

Dataset open option (format specific).

May be repeated.

-f, --of, --format, --output-format <OUTPUT-FORMAT>

Which output raster format to use. Allowed values may be given by `gdal --formats | grep raster | grep rw | sort`

--overwrite

Allow program to overwrite existing target file or dataset. Otherwise, by default, **gdal** errors out if the target file or dataset already exists.

Return status code

The program returns status code 0 in case of success, and non-zero in case of error (non-blocking errors emitted as warnings are considered as a successful execution).

Examples

Example 1: Generates a roughness map from a DTED0 file.

```
$ gdal raster roughness n43.dt0 out.tif --overwrite
```

5.1.3.38 gdal raster scale

Added in version 3.11.

Synopsis

```
Usage: gdal raster scale [OPTIONS] <INPUT> <OUTPUT>

Scale the values of the bands of a raster dataset.

Positional arguments:

Description

gdal raster scale can be used to rescale the input pixels values from the range *--input-min* to *--input-max* to the range *--output-min* to *--output-max*. It is also often necessary to reset the output datatype with the *--ot* switch. If omitted the output range is from the minimum value to the maximum value allowed for integer data types (for example from 0 to 255 for Byte output) or from 0 to 1 for floating-point data types. If omitted the input range is automatically computed from the source dataset. This may be a slow operation on a large source dataset, and if using it multiple times for several gdal_translate invocation, it might be beneficial to call `gdal raster edit --stats {source_dataset}` priorly to precompute statistics, for formats that support serializing statistics computations (GeoTIFF, VRT...) Source values are clipped to the range defined by `srcmin` and `srcmax`, unless *--no-clip* is set.

By default, the scaling is applied to all bands. It is possible to restrict it to a single band with *--band* and leave values of other bands unmodified.

This command is the reverse operation of *gdal raster unscale*.

This subcommand is also available as a potential step of *gdal raster pipeline*

GDALG output (on-the-fly / streamed dataset)

This program supports serializing the command line as a JSON file using the `GDALG` output format. The resulting file can then be opened as a raster dataset using the *GDALG: GDAL Streamed Algorithm* driver, and apply the specified pipeline in a on-the-fly / streamed way.

Program-Specific Options

-b, --band <BAND>

Index (starting at 1) of the band to which the scaling must be only applied.

--exponent <EXPONENT>

Apply non-linear scaling with a power function. `exp_val` is the exponent of the power function (must be positive). This option must be used with the *--input-min* / *--input-max* / *--output-min* / *--output-max* options.

The scaled value `Dst` is calculated from the source value `Src` with the following formula:

$$Dst = (Dst_{max} - Dst_{min}) \times \max\left(0, \min\left(1, \left(\frac{Src - Src_{min}}{Src_{max} - Src_{min}}\right)^{exp_val}\right)\right) + Dst_{min}$$

> **Note**
>
> *gdal raster unscale* assumes linear scaling, and this cannot unscale values back to the original ones.

--input-max <MAX>

Maximum value of the source range. If not specified, it will be calculated from the source dataset. This option must be used together with *--input-min*.

--input-min <MIN>

Minimum value of the source range. If not specified, it will be calculated from the input dataset. This option must be used together with *--input-max*.

--output-max <MAX>

Maximum value of the output range. This option must be used together with *--output-min*.

--output-min <MIN>

Minimum value of the output range. This option must be used together with *--output-max*.

--no-clip

Disable clipping input values to the source range. Note that using this option with non-linear scaling with a non-integer exponent will cause input values lower than the minimum value of the source range to be mapped to not-a-number.

Standard Options

--append

Append input raster as a new subdataset to an existing output file. Only works with drivers that support adding subdatasets such as *GTiff -- GeoTIFF File Format* and *GPKG -- GeoPackage raster* This also creates the output dataset if it does not exist yet.

--co, --creation-option <NAME>=<VALUE>

Many formats have one or more optional creation options that can be used to control particulars about the file created. For instance, the GeoTIFF driver supports creation options to control compression, and whether the file should be tiled.

May be repeated.

The creation options available vary by format driver, and some simple formats have no creation options at all. A list of options supported for a format can be listed with the *--formats* command line option but the documentation for the format is the definitive source of information on driver creation options. See *Raster drivers* format specific documentation for legal creation options for each format.

--if, --input-format <format>

Format/driver name to be attempted to open the input file(s). It is generally not necessary to specify it, but it can be used to skip automatic driver detection, when it fails to select the appropriate driver. This option can be repeated several times to specify several candidate drivers. Note that it does not force those drivers to open the dataset. In particular, some drivers have requirements on file extensions.

May be repeated.

--oo, --open-option <NAME>=<VALUE>

Dataset open option (format specific).

May be repeated.

-f, --of, --format, --output-format <OUTPUT-FORMAT>

Which output raster format to use. Allowed values may be given by `gdal --formats | grep raster | grep rw | sort`

--ot, --datatype, --output-data-type <OUTPUT-DATA-TYPE>

Output data type among `Byte`, `Int8`, `UInt16`, `Int16`, `UInt32`, `Int32`, `UInt64`, `Int64`, `CInt16`, `CInt32`, `Float32`, `Float64`, `CFloat32`, `CFloat64`.

--overwrite

Allow program to overwrite existing target file or dataset. Otherwise, by default, **gdal** errors out if the target file or dataset already exists.

Return status code

The program returns status code 0 in case of success, and non-zero in case of error (non-blocking errors emitted as warnings are considered as a successful execution).

Examples

Example 1: Rescale linearly values of a UInt16 dataset from [0,4095] to a Byte dataset [0,255]

```
$ gdal raster scale --datatype Byte --input-min 0 --input-max 4095 uint16.tif byte.tif --
↪overwrite
```

5.1.3.39 gdal raster select

Added in version 3.11.

Synopsis

```
Usage: gdal raster select [OPTIONS] <INPUT> <OUTPUT> <BAND>

Select a subset of bands from a raster dataset.

Positional arguments:
  -i, --input <INPUT>                                  Input raster datasets [required]␣
↪[not available in pipelines]
  -o, --output <OUTPUT>                                Output raster dataset [required]␣
↪[not available in pipelines]
  -b, --band <BAND>                                    Band(s) (1-based index, 'mask',
↪'mask:<band>' or color interpretation such as 'red') [1.. values] [required]

Common Options:
  -h, --help                                           Display help message and exit
  --json-usage                                         Display usage as JSON document␣
↪and exit
  --config <KEY>=<VALUE>                               Configuration option [may be␣
↪repeated]
  -q, --quiet                                          Quiet mode (no progress bar or␣
↪warning message) [not available in pipelines]

Options:
  -f, --of, --format, --output-format <OUTPUT-FORMAT>  Output format ("GDALG" allowed)␣
↪[not available in pipelines]

  --oo, --open-option <KEY>=<VALUE>                    Open options [may be repeated]␣
↪[not available in pipelines]
```

Description

gdal raster select can be used to select and re-order a subset of raster bands from a raster dataset.

This subcommand is also available as a potential step of *gdal raster pipeline*

GDALG output (on-the-fly / streamed dataset)

This program supports serializing the command line as a JSON file using the GDALG output format. The resulting file can then be opened as a raster dataset using the *GDALG: GDAL Streamed Algorithm* driver, and apply the specified pipeline in a on-the-fly / streamed way.

Program-Specific Options

--exclude

Added in version 3.13.

Modifies the behavior of the algorithm such that all bands are selected, except the ones mentioned by *--band*.

--band <BAND>

Select one or several input bands. Bands are numbered from 1. Multiple values may be selected to select a set of input bands to write to the output file, or to reorder bands. The special value mask means the mask band of the first band of the input dataset. The mask band of any band can be specified with mask:<band>. A mask band selected with --band will become an ordinary band in the output dataset.

Starting with GDAL 3.13, <BAND> can also be a color interpretation such as "red", "green", "blue", "alpha", "nir", etc.

--mask <BAND>

Select one input band to create output dataset mask band.. Bands are numbered from 1. The special value mask means the mask band of the first band of the input dataset. The mask band of any band can be specified with mask:<band>. <BAND> can be set to none to avoid copying the global mask of the input dataset if it exists. Otherwise it is copied by default, unless the mask is an alpha channel, or if it is explicitly selected to be a regular band of the output dataset (--band mask)

Standard Options

--append

Append input raster as a new subdataset to an existing output file. Only works with drivers that support adding subdatasets such as *GTiff -- GeoTIFF File Format* and *GPKG -- GeoPackage raster* This also creates the output dataset if it does not exist yet.

--co, --creation-option <NAME>=<VALUE>

Many formats have one or more optional creation options that can be used to control particulars about the file created. For instance, the GeoTIFF driver supports creation options to control compression, and whether the file should be tiled.

May be repeated.

The creation options available vary by format driver, and some simple formats have no creation options at all. A list of options supported for a format can be listed with the *--formats* command line option but the documentation for the format is the definitive source of information on driver creation options. See *Raster drivers* format specific documentation for legal creation options for each format.

--if, --input-format <format>

Format/driver name to be attempted to open the input file(s). It is generally not necessary to specify it, but it can be used to skip automatic driver detection, when it fails to select the appropriate driver. This option can be repeated several times to specify several candidate drivers. Note that it does not force those drivers to open the dataset. In particular, some drivers have requirements on file extensions.

May be repeated.

--oo, --open-option <NAME>=<VALUE>

Dataset open option (format specific).

May be repeated.

-f, --of, --format, --output-format <OUTPUT-FORMAT>

Which output raster format to use. Allowed values may be given by `gdal --formats | grep raster | grep rw | sort`

--overwrite

Allow program to overwrite existing target file or dataset. Otherwise, by default, **gdal** errors out if the target file or dataset already exists.

Return status code

The program returns status code 0 in case of success, and non-zero in case of error (non-blocking errors emitted as warnings are considered as a successful execution).

Examples

Example 1: Reorder a 3-band dataset with bands ordered Blue, Green, Red to Red, Green, Blue

```
$ gdal raster select --band 3,2,1 bgr.tif rgb.tif --overwrite
```

Example 2: Select input bands by their color interpretation

```
$ gdal raster select --band red,green,blue input.tif rgb.tif --overwrite
```

Example 3: Convert a RGBA dataset to a YCbCR JPEG compressed GeoTIFF

```
$ gdal raster select --band 1,2,3 --mask 4 --co COMPRESS=JPEG,PHOTOMETRIC=YCBCR rgba.tif␣
↪rgb_mask.tif
```

5.1.3.40 gdal raster set-type

Added in version 3.11.

Synopsis

```
Usage: gdal raster set-type [OPTIONS] <INPUT> <OUTPUT>

Modify the data type of bands of a raster dataset.

Positional arguments:
  -i, --input <INPUT>                                       Input raster datasets␣
↪[required] [not available in pipelines]
  -o, --output <OUTPUT>                                     Output raster dataset␣
↪[required] [not available in pipelines]

Common Options:
  -h, --help                                                Display help message and exit
  --json-usage                                              Display usage as JSON␣
↪document and exit
  --config <KEY>=<VALUE>                                    Configuration option [may be␣
↪repeated]

  --oo, --open-option <KEY>=<VALUE>                         Open options [may be␣
↪repeated] [not available in pipelines]
```

Description

gdal raster set-type can be used to force the output image bands to have a specific data type. Values may be truncated or rounded if the output data type is "smaller" than the input one.

This subcommand is also available as a potential step of *gdal raster pipeline*

GDALG output (on-the-fly / streamed dataset)

This program supports serializing the command line as a JSON file using the `GDALG` output format. The resulting file can then be opened as a raster dataset using the *GDALG: GDAL Streamed Algorithm* driver, and apply the specified pipeline in a on-the-fly / streamed way.

Program-Specific Options

--ot, --datatype, --output-data-type <OUTPUT-DATA-TYPE>

Output data type among `Byte`, `Int8`, `UInt16`, `Int16`, `UInt32`, `Int32`, `UInt64`, `Int64`, `CInt16`, `CInt32`, `Float32`, `Float64`, `CFloat32`, `CFloat64`.

Standard Options

--co, --creation-option <NAME>=<VALUE>

Many formats have one or more optional creation options that can be used to control particulars about the file created. For instance, the GeoTIFF driver supports creation options to control compression, and whether the file should be tiled.

May be repeated.

The creation options available vary by format driver, and some simple formats have no creation options at all. A list of options supported for a format can be listed with the *--formats* command line option but the documentation for the format is the definitive source of information on driver creation options. See *Raster drivers* format specific documentation for legal creation options for each format.

-f, --of, --format, --output-format <OUTPUT-FORMAT>

Which output raster format to use. Allowed values may be given by `gdal --formats | grep raster | grep rw | sort`

--overwrite

Allow program to overwrite existing target file or dataset. Otherwise, by default, **gdal** errors out if the target file or dataset already exists.

Return status code

The program returns status code 0 in case of success, and non-zero in case of error (non-blocking errors emitted as warnings are considered as a successful execution).

Examples

Example 1: Convert to Float32 data type

```
$ gdal raster set-type --datatype Float32 byte.tif float32.tif --overwrite
```

5.1.3.41 gdal raster slope

Added in version 3.11.

Synopsis

```
Usage: gdal raster slope [OPTIONS] <INPUT> <OUTPUT>

Generate a slope map
```

```

Description

gdal raster slope generates a slope map, from any GDAL-supported elevation raster.

This subcommand is also available as a potential step of *gdal raster pipeline*

It generates a 32-bit float raster with slope values. You have the option of specifying the type of slope value you want: degrees or percent slope. In cases where the horizontal units differ from the vertical units, you can also supply scaling factors to account for differences between vertical and horizontal units.

The value *-9999* is used as the output nodata value. A nodata value in the target dataset will be emitted if at least one pixel set to the nodata value is found in the 3x3 window centered around each source pixel. By default, the algorithm will compute values at image edges or if a nodata value is found in the 3x3 window, by interpolating missing values, unless `--no-edges` is specified, in which case a 1-pixel border around the image will be set with the nodata value.

In general, it assumes that x, y and z units are identical. However, if none of `--xscale` and `--yscale` are specified, and the CRS is a geographic or projected CRS, it will automatically determine the appropriate ratio from the units of the CRS, as well as the potential value of the units of the raster band (as returned by `GDALRasterBand::GetUnitType()`, if it is metre, foot international or US survey foot). Note that for geographic CRS, the result for source datasets at high latitudes may be incorrect, and prior reprojection to a polar projection might be needed using *gdal raster reproject*.

If x (east-west) and y (north-south) units are identical, but z (elevation) units are different, the `--xscale` and `--yscale` can be used to set the ratio of vertical units to horizontal. For geographic CRS near the equator, where units of latitude and units of longitude are similar, elevation (z) units can be converted to be compatible by using scale=370400 (if elevation is in feet) or scale=111120 (if elevation is in meters). For locations not near the equator, the `--xscale` value can be taken as the `--yscale` value multiplied by the cosine of the mean latitude of the raster.

GDALG output (on-the-fly / streamed dataset)

This program supports serializing the command line as a JSON file using the `GDALG` output format. The resulting file can then be opened as a raster dataset using the *GDALG: GDAL Streamed Algorithm* driver, and apply the specified pipeline in a on-the-fly / streamed way.

Program-Specific Options

-b, --band <BAND>

Index (starting at 1) of the band to which the slope must be computed.

--gradient-alg `Horn|ZevenbergenThorne`

Algorithm used to compute terrain gradient. The default is `Horn`. The literature suggests Zevenbergen & Thorne to be more suited to smooth landscapes, whereas Horn's formula to perform better on rougher terrain.

--no-edges

Do not try to interpolate values at dataset edges or close to nodata values

--unit `degree|percent`

Unit in which to express slopes. Defaults to `degree`.

--xscale <scale>

Ratio of vertical units to horizontal X axis units. If the horizontal unit of the source DEM is degrees (e.g Lat/Long WGS84 projection), you can use scale=111120 if the vertical units are meters (or scale=370400 if they are in feet).

If none of `--xscale` and `--yscale` are specified, and the CRS is a geographic or projected CRS, **gdal raster slope** will automatically determine the appropriate ratio from the units of the CRS, as well as the potential value of the units of the raster band (as returned by `GDALRasterBand::GetUnitType()`, if it is metre, foot international or US survey foot). Note that for geographic CRS, the result for source datasets at high latitudes may be incorrect, and prior reprojection to a polar projection might be needed.

If `--xscale` is specified, `--yscale` must also be specified.

--yscale <scale>

Ratio of vertical units to horizontal Y axis units. If the horizontal unit of the source DEM is degrees (e.g Lat/Long

WGS84 projection), you can use scale=111120 if the vertical units are meters (or scale=370400 if they are in feet)

If none of `--xscale` and `--yscale` are specified, and the CRS is a geographic or projected CRS, **gdal raster slope** will automatically determine the appropriate ratio from the units of the CRS, as well as the potential value of the units of the raster band (as returned by *GDALRasterBand::GetUnitType()*, if it is metre, foot international or US survey foot). Note that for geographic CRS, the result for source datasets at high latitudes may be incorrect, and prior reprojection to a polar projection might be needed.

If `--yscale` is specified, `--xscale` must also be specified.

Standard Options

--append

Append input raster as a new subdataset to an existing output file. Only works with drivers that support adding subdatasets such as *GTiff -- GeoTIFF File Format* and *GPKG -- GeoPackage raster* This also creates the output dataset if it does not exist yet.

--co, --creation-option <NAME>=<VALUE>

Many formats have one or more optional creation options that can be used to control particulars about the file created. For instance, the GeoTIFF driver supports creation options to control compression, and whether the file should be tiled.

May be repeated.

The creation options available vary by format driver, and some simple formats have no creation options at all. A list of options supported for a format can be listed with the *--formats* command line option but the documentation for the format is the definitive source of information on driver creation options. See *Raster drivers* format specific documentation for legal creation options for each format.

--if, --input-format <format>

Format/driver name to be attempted to open the input file(s). It is generally not necessary to specify it, but it can be used to skip automatic driver detection, when it fails to select the appropriate driver. This option can be repeated several times to specify several candidate drivers. Note that it does not force those drivers to open the dataset. In particular, some drivers have requirements on file extensions.

May be repeated.

--oo, --open-option <NAME>=<VALUE>

Dataset open option (format specific).

May be repeated.

-f, --of, --format, --output-format <OUTPUT-FORMAT>

Which output raster format to use. Allowed values may be given by `gdal --formats | grep raster | grep rw | sort`

--overwrite

Allow program to overwrite existing target file or dataset. Otherwise, by default, **gdal** errors out if the target file or dataset already exists.

Return status code

The program returns status code 0 in case of success, and non-zero in case of error (non-blocking errors emitted as warnings are considered as a successful execution).

Examples

Example 1: Generates a slope map from a DTED0 file.

```
$ gdal raster slope n43.dt0 out.tif --overwrite
```

5.1.3.42 gdal raster sieve

Added in version 3.11.

Synopsis

```
Usage: gdal raster sieve [OPTIONS] <INPUT> <OUTPUT>

Remove small polygons from a raster dataset.

Positional arguments:
  -i, --input <INPUT>                                    Input raster datasets [required]␣
↪[not available in pipelines]

```

Description

gdal raster sieve removes raster polygons smaller than a provided threshold size (in pixels) and replaces them with the pixel value of the largest neighbour polygon.

The input dataset is read as integer data which means that floating point values are rounded to integers. Re-scaling source data may be necessary in some cases (e.g. 32-bit floating point data with min=0 and max=1).

This subcommand is also available as a potential step of *gdal raster pipeline* (since GDAL 3.12)

Added in version 3.12.

GDALG output (on-the-fly / streamed dataset)

This program supports serializing the command line as a JSON file using the `GDALG` output format. The resulting file can then be opened as a raster dataset using the *GDALG: GDAL Streamed Algorithm* driver, and apply the specified pipeline in a on-the-fly / streamed way.

> **Note**
>
> However this algorithm is not natively streaming compatible. Consequently a temporary dataset will be generated, which may cause significant processing time at opening.

Program-Specific Options

-b, --band `<BAND>`

Input band (1-based index)

-c, --connect-diagonal-pixels

Consider diagonal pixels (pixels at the corners) as connected. The default behavior is to only consider pixels that are touching the edges as connected, which is the same as 4-connectivity. When this option is selected, the algorithm will also consider pixels at the corners as connected, which is the same as 8-connectivity.

--mask `<MASK>`

Use the first band of the specified file as a validity mask: all pixels in the mask band with a value other than zero will be considered suitable for inclusion in polygons.

-s, --size-threshold `<SIZE-THRESHOLD>`

Minimum size of polygons to keep (default: 2)

Standard Options

--append

Append input raster as a new subdataset to an existing output file. Only works with drivers that support adding subdatasets such as *GTiff -- GeoTIFF File Format* and *GPKG -- GeoPackage raster* This also creates the output dataset if it does not exist yet.

--co, --creation-option <NAME>=<VALUE>

Many formats have one or more optional creation options that can be used to control particulars about the file created. For instance, the GeoTIFF driver supports creation options to control compression, and whether the file should be tiled.

May be repeated.

The creation options available vary by format driver, and some simple formats have no creation options at all. A list of options supported for a format can be listed with the *--formats* command line option but the documentation for the format is the definitive source of information on driver creation options. See *Raster drivers* format specific documentation for legal creation options for each format.

--if, --input-format <format>

Format/driver name to be attempted to open the input file(s). It is generally not necessary to specify it, but it can be used to skip automatic driver detection, when it fails to select the appropriate driver. This option can be repeated several times to specify several candidate drivers. Note that it does not force those drivers to open the dataset. In particular, some drivers have requirements on file extensions.

May be repeated.

--oo, --open-option <NAME>=<VALUE>

Dataset open option (format specific).

May be repeated.

-f, --of, --format, --output-format <OUTPUT-FORMAT>

Which output raster format to use. Allowed values may be given by `gdal --formats | grep raster | grep rw | sort`

--overwrite

Allow program to overwrite existing target file or dataset. Otherwise, by default, **gdal** errors out if the target file or dataset already exists.

Return status code

The program returns status code 0 in case of success, and non-zero in case of error (non-blocking errors emitted as warnings are considered as a successful execution).

Examples

Example 1: Remove polygons smaller than 10 pixels from the band 2 of a raster.

```
$ gdal raster sieve -b 2 -s 10 input.tif output.tif
```

5.1.3.43 gdal raster stack

Added in version 3.11.

Synopsis

```
Usage: gdal raster stack [OPTIONS] <INPUTS>... <OUTPUT>

Combine together input bands into a multi-band output, either virtual (VRT) or␣
↪materialized.
```

```

Description

This program combine together input bands from GDAL datasets into a dataset, that can be either a virtual stack in the *VRT (Virtual Dataset)* format, or in a more conventional raster format such as GeoTIFF.

All bands of each input file are added as separate output bands, unless `-b` is specified to select a subset of them.

The list of input GDAL datasets can be specified at the end of the command line or put in a text file (one filename per line) for very long lists. Wildcards '*', '?' or '[' of `VSIGlob()` can be used, even on files located on network file systems such as /vsis3/, /vsigs/, /vsiaz/, etc.

Stating with GDAL 3.12, this command can also be used as the first step of *gdal raster pipeline*.

GDALG output (on-the-fly / streamed dataset)

This program supports serializing the command line as a JSON file using the `GDALG` output format. The resulting file can then be opened as a raster dataset using the *GDALG: GDAL Streamed Algorithm* driver, and apply the specified pipeline in a on-the-fly / streamed way.

Program-Specific Options

--absolute-path

Added in version 3.12.0.

When writing a VRT file, enables writing the absolute path of the input datasets. By default, input filenames are written in a relative way with respect to the VRT filename (when possible).

-b, --band <band>

Select an input <band> to be processed. Bands are numbered from 1. If input bands not set all bands will be added to the output. Multiple `-b` switches may be used to select a set of input bands.

--bbox <xmin>,<ymin>,<xmax>,<ymax>

Set georeferenced extents of output file. The values must be expressed in georeferenced units. If not specified, the extent of the output is the minimum bounding box of the set of source rasters. Pixels within the extent of the output but not covered by a source raster will be read as valid pixels with a value of zero unless a NODATA value is specified using `--output-nodata`.

--hide-nodata

Even if any band contains nodata value, giving this option makes the output band not report the NoData. Useful when you want to control the background color of the dataset.

--input-nodata <value>[,<value>]...

Set nodata values for input bands (different values can be supplied for each band). If the option is not specified, the intrinsic nodata settings on the source datasets will be used (if they exist). The value set by this option is written in the NODATA element of each `ComplexSource` element.

--output-nodata <value>[,<value>]...

Set nodata values at the output band level (different values can be supplied for each band). If more than one value is supplied, all values should be quoted to keep them together as a single operating system argument. If the option is not specified, intrinsic nodata settings on the first dataset will be used (if they exist). The value set by this option is written in the `NoDataValue` element of each `VRTRasterBand element`. Use a value of *None* to ignore intrinsic nodata settings on the source datasets.

--resolution {<xres,yres>|same|highest|lowest|average}

In case the resolution of all input files is not the same, the `--resolution` flag enables the user to control the way the output resolution is computed.

same, the default, checks that all source rasters have the same resolution and errors out when this is not the case.

highest will pick the smallest values of pixel dimensions within the set of source rasters.

lowest will pick the largest values of pixel dimensions within the set of source rasters.

average will compute an average of pixel dimensions within the set of source rasters.

common determines the greatest common divisor of the source pixel dimensions, e.g. 0.2 for source pixel dimensions of 0.4 and 0.6.

<xres>,<yres>. The values must be expressed in georeferenced units. Both must be positive values.

--target-aligned-pixels

(target aligned pixels) align the coordinates of the extent of the output file to the values of the `--resolution`, such that the aligned extent includes the minimum extent. Alignment means that xmin / resx, ymin / resy, xmax / resx and ymax / resy are integer values.

Standard Options

--append

Append input raster as a new subdataset to an existing output file. Only works with drivers that support adding subdatasets such as *GTiff -- GeoTIFF File Format* and *GPKG -- GeoPackage raster* This also creates the output dataset if it does not exist yet.

--co, --creation-option <NAME>=<VALUE>

Many formats have one or more optional creation options that can be used to control particulars about the file created. For instance, the GeoTIFF driver supports creation options to control compression, and whether the file should be tiled.

May be repeated.

The creation options available vary by format driver, and some simple formats have no creation options at all. A list of options supported for a format can be listed with the *--formats* command line option but the documentation for the format is the definitive source of information on driver creation options. See *Raster drivers* format specific documentation for legal creation options for each format.

--if, --input-format <format>

Format/driver name to be attempted to open the input file(s). It is generally not necessary to specify it, but it can be used to skip automatic driver detection, when it fails to select the appropriate driver. This option can be repeated several times to specify several candidate drivers. Note that it does not force those drivers to open the dataset. In particular, some drivers have requirements on file extensions.

May be repeated.

--oo, --open-option <NAME>=<VALUE>

Dataset open option (format specific).

May be repeated.

-f, --of, --format, --output-format <OUTPUT-FORMAT>

Which output raster format to use. Allowed values may be given by `gdal --formats | grep raster | grep rw | sort`

--overwrite

Allow program to overwrite existing target file or dataset. Otherwise, by default, **gdal** errors out if the target file or dataset already exists.

Return status code

The program returns status code 0 in case of success, and non-zero in case of error (non-blocking errors emitted as warnings are considered as a successful execution).

Examples

Example 1: Make a RGB stack from 3 single-band input files

```
gdal raster stack red.tif green.tif blue.tif rgb.tif
```

Example 2: Make a virtual (VRT) stack from 2 single-band input files

```
gdal raster stack raster1.tif raster2.tif result.vrt
```

5.1.3.44 gdal raster tile

Added in version 3.11.

Synopsis

```
Usage: gdal raster tile [OPTIONS] <INPUT> <OUTPUT>

Generate tiles in separate files from a raster dataset.

Description

gdal raster tile generates a directory with small tiles and metadata, following the OGC WMTS Specification. Simple web pages with viewers based on OpenLayers and Leaflet are generated as well - so anybody can comfortably explore your maps on-line and you do not need to install or configure any special software (like MapServer) and the map displays very fast in the web browser. You only need to upload the generated directory onto a web server.

It generates PNG files by default, but other output formats can be selected (JPEG, WEBP, GTiff, etc.). Note that not all formats support non-Byte data types. JPEG and WEBP only support Byte. PNG supports Byte and UInt16. GeoTiff can support all data types.

It can also use a tiling scheme fully adapted to the input raster, in terms of origin and resolution, when using the `raster` tiling scheme. In that scheme, tiles at the maximum zoom level will have the same resolution as the raster.

Starting with GDAL 3.12, **gdal raster tile** can be used as the last step of a pipeline.

Program-Specific Options

--aux-xml

Generate .aux.xml sidecar files when needed

--add-alpha

Whether to force adding an alpha channel. An alpha channel is added by default, unless the source dataset has a nodata value and the output format supports it.

--copy-src-metadata

Whether to copy metadata from source dataset into output tiles.

--convention `xyz|tms`

Tile numbering convention:

- `xyz` (default): from top, as in OGC Web Map Tiling Specification (WMTS)

- `tms`: from bottom, as in OSGeo Tile Map Service (TMS) Specification.

--output-nodata <NODATA>

Output nodata value.

-i, --input <INPUT>

Input raster dataset [required]

--kml

Generate Google Earth SuperOverlay metadata. Not compatible with tiling schemes with non-power-of-two zoom levels.

--max-x <MAX-X>

Maximum tile X coordinate, at maximum zoom level. Can be set to restrict the tiling process.

--max-y <MAX-Y>

Maximum tile Y coordinate, at maximum zoom level. Can be set to restrict the tiling process.

--max-zoom <MAX-ZOOM>

Maximum zoom level to generate. If not specified, this will be determined by comparing the resolution of the input dataset with the closest resolution in the list of tile matrix of the tile matrix set.

--metadata <KEY>=<VALUE>

Add metadata item to output tiles [may be repeated]

--min-x <MIN-X>

Minimum tile X coordinate, at maximum zoom level. Can be set to restrict the tiling process.

--min-y <MIN-Y>

Minimum tile Y coordinate, at maximum zoom level. Can be set to restrict the tiling process.

--min-zoom <MIN-ZOOM>

Minimum zoom level to generate. If not specified, equal to *--max-zoom*.

--no-alpha

Disable the creation of an alpha channel.

--no-intersection-ok

Whether the dataset extent not intersecting the tile matrix is only a warning. Otherwise, by default, an error will be emitted if that occurs.

-j, --num-threads <value>

Number of jobs to run at once. Default: number of CPUs detected.

-o, --output <OUTPUT>

Output directory [required]

The directory will be created if it does not exist, but its parent directory must exist.

--overview-resampling `nearest|bilinear|cubic|cubicspline|lanczos|average|rms|mode|min|max|med|q1|q3|sum`

Resampling method used to generate zoom levels lower than the maximum zoom level. Defaults to the value of *--resampling* is not specified.

--parallel-method `thread|spawn|fork`

Added in version GDAL: 3.12

Parallelization method:

- `thread` uses multi-threading, i.e. parallelized tasks are run within the same process.

- `spawn` launches child **gdal** sub-processes. `spawn` can achieve better "scaling", but requires the **gdal** binary to be available. GDAL will try to locate it, but you can also set the `GDAL_PATH` configuration option to point to the directory where the **gdal** binary is located.
- `fork` is a variant of `spawn`, using the system call `fork`, without executing the the **gdal** binary. Such method is not available on Windows. On Unix systems where it is available, this method is not recommended to be used on multithreaded processes, especially the ones where other threads are doing GDAL operation, since it can potentially cause deadlocks.

If *--parallel-method* is not specified, GDAL will automatically decide which of the method is the most appropriate, opting for `spawn` if the **gdal** binary can be located and a sufficient number of tiles per job are generated, and otherwise falling back to `fork` on Linux, MacOSX or FreeBSD (if no other thread is running), and otherwise to `thread`.

-r,
--resampling `nearest|bilinear|cubic|cubicspline|lanczos|average|rms|mode|min|max|med|q1|q3|sum`

Resampling method used to generate maximum zoom level, and also lower zoom levels if *--overview-resampling* is not specified. Defaults to `cubic`.

--resume

Generate only missing files. Can be used when interrupting a previous run to restart it.

--skip-blank

Do not generate fully blank/transparent tiles.

--tile-size `<PIXELS>`

Width and height of a tile, in pixels. Default is 256 for default tiling schemes. Setting it to a higher value enables generating higher DPI tile sets.

--tiling-scheme `<TILING-SCHEME>`

Tile cutting scheme. Defaults to WebMercatorQuad (also known as Google Maps compatible).

The following base profiles are available:

- `raster`: CRS = CRS of raster, tile size = 256 pixels, raster coverage at all zoom levels.
- `WebMercatorQuad`: CRS = EPSG:3857 ("WGS 84 / Pseudo-Mercator"), tile size: 256 pixels, whole world coverage at zoom level 0, one single tile at zoom level 0.
- `WorldCRS84Quad`: CRS = EPSG:4326 ("WGS 84"), tile size: 256 pixels, whole world coverage at zoom level 0, two side-by-side tiles at zoom level 0
- `WorldMercatorWGS84Quad`: CRS = EPSG:3395 ("WGS 84 / World Mercator"), tile size: 256 pixels, whole world coverage at zoom level 0, one single tile at zoom level 0. This can be seen as a variant of WebMercatorQuad except that it is fully conformal on the WGS84 ellipsoid.
- `GoogleCRS84Quad`: CRS = EPSG:4326 ("WGS 84"), tile size: 256 pixels, whole world coverage at zoom level 0, one single tile at zoom level 0 whose first and last 64 lines are blank (the top origin of the tile is a pseudo latitude of 180 degree, and its bottom -180 degree).
- `PseudoTMS_GlobalMercator`: CRS = EPSG:3857 ("WGS 84 / Pseudo-Mercator"), tile size: 256 pixels, whole world coverage at zoom level 0, 2x2 tiles at zoom level 0. This is equivalent to `WebMercatorQuad`, but with the zoom level shifted by one.
- `LINZAntarticaMapTileGrid`: LINZ Antarctic Map Tile Grid (Ross Sea Region). See tms_LINZAntarticaMapTileGrid.json
- `APSTILE`: Alaska Polar Stereographic-based tiled coordinate reference system for the Arctic region. See tms_MapML_APSTILE.json

- `CBMTILE`: Lambert Conformal Conic-based tiled coordinate reference system for Canada. See tms_MapML_CBMTILE.json
- `NZTM2000`: LINZ NZTM2000 Map Tile Grid. See tms_NZTM2000.json

Additional tiling schemes are discovered from `tms_XXXX.json` files placed in the GDAL data directory.

Advanced Resampling Options

--excluded-values=<EXCLUDED-VALUES>

Comma-separated tuple of values (thus typically "R,G,B"), that are ignored as contributing source pixels during resampling. The number of values in the tuple must be the same as the number of bands, excluding the alpha band. Several tuples of excluded values may be specified using the "(R1,G1,B2),(R2,G2,B2)" syntax. Only taken into account for average resampling. This concept is a bit similar to nodata/alpha, but the main difference is that pixels matching one of the excluded value tuples are still considered as valid, when determining the target pixel validity/density.

Added in version 3.11.1.

--excluded-values-pct-threshold=<EXCLUDED-VALUES-PCT-THRESHOLD>

Minimum percentage of source pixels that must be set at one of the --excluded-values to cause the excluded value, that is in majority among source pixels, to be used as the target pixel value. Default value is 50(%)

Added in version 3.11.1.

--nodata-values-pct-threshold=<NODATA-VALUES-PCT-THRESHOLD>

Minimum percentage of source pixels that must be at nodata (or alpha=0 or any other way to express transparent pixel) to cause the target pixel value to be transparent. Default value is 100 (%), which means that a target pixel is transparent only if all contributing source pixels are transparent. Only taken into account for average resampling.

Added in version 3.11.1.

Publication Options

--webviewer none|all|leaflet|openlayers|mapml|stac

Web viewer to generate. Defaults to `all`. Those web viewers are created at the root of the output directory.

`stac` generates a `stacta.json` file, following the Spatio-Temporal Asset Catalog Tiled Assets specification, and that can be opened by the *STACTA driver*.

--url

URL address where the generated tiles are going to be published.

--title <TITLE>

Title of the map.

--copyright <COPYRIGHT>

Copyright for the map.

MapML options

MapML webviewer can only be generated if *--convention* is set to the default value `xyz`.

The following profiles are supported:

- `WebMercatorQuad`: mapped to OSMTILE MapML tiling scheme
- `GoogleCRS84Quad`: mapped to WGS84 MapML tiling scheme
- `APSTILE`: from the tms_MapML_APSTILE.json data file

- CBMTILE: from the tms_MapML_CBMTILE.json data file

The generated MapML file in the output directory is `mapml.mapl`

Available options are:

--mapml-template <filename>

Filename of a template mapml file where variables will be substituted. If not specified, the generic template_tiles.mapml file from GDAL data resources will be used

The *--url* option is also used to substitute ${URL} in the template MapML file.

Standard Options

--co, --creation-option <NAME>=<VALUE>

Many formats have one or more optional creation options that can be used to control particulars about the file created. For instance, the GeoTIFF driver supports creation options to control compression, and whether the file should be tiled.

May be repeated.

The creation options available vary by format driver, and some simple formats have no creation options at all. A list of options supported for a format can be listed with the *--formats* command line option but the documentation for the format is the definitive source of information on driver creation options. See *Raster drivers* format specific documentation for legal creation options for each format.

--if, --input-format <format>

Format/driver name to be attempted to open the input file(s). It is generally not necessary to specify it, but it can be used to skip automatic driver detection, when it fails to select the appropriate driver. This option can be repeated several times to specify several candidate drivers. Note that it does not force those drivers to open the dataset. In particular, some drivers have requirements on file extensions.

May be repeated.

--oo, --open-option <NAME>=<VALUE>

Dataset open option (format specific).

May be repeated.

-f, --of, --format, --output-format <OUTPUT-FORMAT>

Which output raster format to use. Allowed values may be given by `gdal --formats | grep raster | grep rw | sort`

Defaults to PNG.

Return status code

The program returns status code 0 in case of success, and non-zero in case of error (non-blocking errors emitted as warnings are considered as a successful execution).

Examples

Example 1: Generate PNG tiles with WebMercatorQuad tiling scheme for zoom levels 2 to 5.

```
gdal raster tile --min-zoom=2 --max-zoom=5 input.tif output_folder
```

Example 2: Retile a raster using its origin and resolution

```
gdal raster tile --tiling-scheme raster input.tif output_folder
```

Example 3: Creating a tiled dataset, compatible with the Spatio-Temporal Asset Catalog Tiled Assets specification, using Cloud-Optimized GeoTIFF metatiles of dimension 4096x4096.

```
gdal raster tile --format COG --tile-size 4096 input.tif output_folder
```

Example 4: Mosaic on-the-fly several input files and tile that mosaic.

```
gdal raster pipeline ! mosaic input*.tif ! tile output_folder
```

5.1.3.45 gdal raster tpi

Added in version 3.11.

Synopsis

```
Usage: gdal raster tpi [OPTIONS] <INPUT> <OUTPUT>

Generate a Topographic Position Index (TPI) map

Positional arguments:
  -i, --input <INPUT>                                    Input raster datasets [required]␣

```

Description

gdal raster tpi generates a single-band raster with values computed from the elevation. TPI stands for Topographic Position Index, which is defined as the difference between a central pixel and the mean of its surrounding cells (see Wilson et al 2007, Marine Geodesy 30:3-35).

This subcommand is also available as a potential step of *gdal raster pipeline*

Value -9999 is used as the nodata value.

A nodata value in the target dataset will also be emitted if at least one pixel set to the nodata value is found in the 3x3 window centered around each source pixel. By default, the algorithm will compute values at image edges or if a nodata value is found in the 3x3 window, by interpolating missing values, unless `--no-edges` is specified, in which case a 1-pixel border around the image will be set with the nodata value.

GDALG output (on-the-fly / streamed dataset)

This program supports serializing the command line as a JSON file using the `GDALG` output format. The resulting file can then be opened as a raster dataset using the *GDALG: GDAL Streamed Algorithm* driver, and apply the specified pipeline in a on-the-fly / streamed way.

Program-Specific Options

-b, --band <BAND>

Index (starting at 1) of the band to which the TPI must be computed.

--no-edges

Do not try to interpolate values at dataset edges or close to nodata values

Standard Options

--append

Append input raster as a new subdataset to an existing output file. Only works with drivers that support adding subdatasets such as *GTiff -- GeoTIFF File Format* and *GPKG -- GeoPackage raster* This also creates the output dataset if it does not exist yet.

--co, --creation-option <NAME>=<VALUE>

Many formats have one or more optional creation options that can be used to control particulars about the file created. For instance, the GeoTIFF driver supports creation options to control compression, and whether the file should be tiled.

May be repeated.

The creation options available vary by format driver, and some simple formats have no creation options at all. A list of options supported for a format can be listed with the *--formats* command line option but the documentation

for the format is the definitive source of information on driver creation options. See *Raster drivers* format specific documentation for legal creation options for each format.

--if, --input-format <format>

Format/driver name to be attempted to open the input file(s). It is generally not necessary to specify it, but it can be used to skip automatic driver detection, when it fails to select the appropriate driver. This option can be repeated several times to specify several candidate drivers. Note that it does not force those drivers to open the dataset. In particular, some drivers have requirements on file extensions.

May be repeated.

--oo, --open-option <NAME>=<VALUE>

Dataset open option (format specific).

May be repeated.

-f, --of, --format, --output-format <OUTPUT-FORMAT>

Which output raster format to use. Allowed values may be given by `gdal --formats | grep raster | grep rw | sort`

--overwrite

Allow program to overwrite existing target file or dataset. Otherwise, by default, **gdal** errors out if the target file or dataset already exists.

Return status code

The program returns status code 0 in case of success, and non-zero in case of error (non-blocking errors emitted as warnings are considered as a successful execution).

Examples

Example 1: Generates a Topographic Position Index (TPI) map from a DTED0 file.

```
$ gdal raster tpi n43.dt0 out.tif --overwrite
```

5.1.3.46 gdal raster tri

Added in version 3.11.

Synopsis

```
Usage: gdal raster tri [OPTIONS] <INPUT> <OUTPUT>

Generate a Terrain Ruggedness Index (TRI) map

Positional arguments:
  -i, --input <INPUT>                                    Input raster datasets [required]␣
↪[not available in pipelines]
  -o, --output <OUTPUT>                                  Output raster dataset [required]␣

↪[not available in pipelines]
```

Description

gdal raster tri generates a single-band raster with values computed from the elevation. TRI stands for Terrain Ruggedness Index, which measures the difference between a central pixel and its surrounding cells.

This subcommand is also available as a potential step of *gdal raster pipeline*

Value -9999 is used as the nodata value.

A nodata value in the target dataset will also be emitted if at least one pixel set to the nodata value is found in the 3x3 window centered around each source pixel. By default, the algorithm will compute values at image edges or if a nodata value is found in the 3x3 window, by interpolating missing values, unless `--no-edges` is specified, in which case a 1-pixel border around the image will be set with the nodata value.

GDALG output (on-the-fly / streamed dataset)

This program supports serializing the command line as a JSON file using the `GDALG` output format. The resulting file can then be opened as a raster dataset using the *GDALG: GDAL Streamed Algorithm* driver, and apply the specified pipeline in a on-the-fly / streamed way.

Program-Specific Options

--algorithm `Riley|Wilson`

Select the algorithm to use:

- `Riley`, the default, uses the square root of the sum of the square of the difference between a central pixel and its surrounding cells. This is recommended for terrestrial use cases. It is implemented from Riley, S.J., De Gloria, S.D., Elliot, R. (1999): A Terrain Ruggedness that Quantifies Topographic Heterogeneity. Intermountain Journal of Science, Vol.5, No.1-4, pp.23-27
- `Wilson` uses the mean difference between a central pixel and its surrounding cells. This is recommended for bathymetric use cases. It is implemented from Wilson et al. 2007, Marine Geodesy 30:3-35.

-b, --band `<BAND>`

Index (starting at 1) of the band to which the TRI must be computed.

--no-edges

Do not try to interpolate values at dataset edges or close to nodata values

Standard Options

--append

Append input raster as a new subdataset to an existing output file. Only works with drivers that support adding subdatasets such as *GTiff -- GeoTIFF File Format* and *GPKG -- GeoPackage raster* This also creates the output dataset if it does not exist yet.

--co, --creation-option `<NAME>=<VALUE>`

Many formats have one or more optional creation options that can be used to control particulars about the file created. For instance, the GeoTIFF driver supports creation options to control compression, and whether the file should be tiled.

May be repeated.

The creation options available vary by format driver, and some simple formats have no creation options at all. A list of options supported for a format can be listed with the *--formats* command line option but the documentation for the format is the definitive source of information on driver creation options. See *Raster drivers* format specific documentation for legal creation options for each format.

--if, --input-format `<format>`

Format/driver name to be attempted to open the input file(s). It is generally not necessary to specify it, but it can be used to skip automatic driver detection, when it fails to select the appropriate driver. This option can be repeated several times to specify several candidate drivers. Note that it does not force those drivers to open the dataset. In particular, some drivers have requirements on file extensions.

May be repeated.

--oo, --open-option `<NAME>=<VALUE>`

Dataset open option (format specific).

May be repeated.

-f, --of, --format, --output-format `<OUTPUT-FORMAT>`

Which output raster format to use. Allowed values may be given by `gdal --formats | grep raster | grep rw | sort`

--overwrite

Allow program to overwrite existing target file or dataset. Otherwise, by default, **gdal** errors out if the target file or dataset already exists.

Return status code

The program returns status code 0 in case of success, and non-zero in case of error (non-blocking errors emitted as warnings are considered as a successful execution).

Examples

Example 1: Generates a Terrain Ruggedness Index (TRI) map from a DTED0 file.

```
$ gdal raster tri n43.dt0 out.tif --overwrite
```

5.1.3.47 gdal raster unscale

Added in version 3.11.

Synopsis

```
Usage: gdal raster unscale [OPTIONS] <INPUT> <OUTPUT>

Convert scaled values of a raster dataset into unscaled values.

Positional arguments:
  -i, --input <INPUT>                                       Input raster datasets␣
↪[required] [not available in pipelines]
  -o, --output <OUTPUT>                                     Output raster dataset␣
↪[required] [not available in pipelines]

Common Options:
  -h, --help                                                Display help message and exit
  --json-usage                                              Display usage as JSON␣
↪document and exit
  --config <KEY>=<VALUE>                                    Configuration option [may be␣
↪repeated]
  -q, --quiet                                               Quiet mode (no progress bar␣
↪or warning message) [not available in pipelines]

Options:
  -f, --of, --format, --output-format <OUTPUT-FORMAT>       Output format ("GDALG"␣
↪allowed) [not available in pipelines]
  --co, --creation-option <KEY>=<VALUE>                     Creation option [may be␣
↪repeated] [not available in pipelines]

Description

gdal raster unscale applies the scale/offset metadata for the bands to convert scaled values to unscaled values.

If the input band data type is Byte, Int8, UInt16, Int16, UInt32, Int32, Int64, UInt64, Float16 or Float32, the default output data type will be Float32. If the input band data type is Float64, it will be kept as the default output data type. If the input band data type is CInt16, CFloat16 or CFloat32, the default output data type will be Float32. If the input band data type is CFloat64, it will be kept as the default output data type.

The unscaled value is computed from the scaled raw value with the following formula:

$$unscaled_value = scaled_value * scale + offset$$

If one of the input bands has no scale/offset metadata, its values are kept unmodified.

This command is the reverse operation of *gdal raster scale*.

This subcommand is also available as a potential step of *gdal raster pipeline*

GDALG output (on-the-fly / streamed dataset)

This program supports serializing the command line as a JSON file using the `GDALG` output format. The resulting file can then be opened as a raster dataset using the *GDALG: GDAL Streamed Algorithm* driver, and apply the specified pipeline in a on-the-fly / streamed way.

Standard Options

--append

Append input raster as a new subdataset to an existing output file. Only works with drivers that support adding subdatasets such as *GTiff -- GeoTIFF File Format* and *GPKG -- GeoPackage raster* This also creates the output dataset if it does not exist yet.

--co, --creation-option <NAME>=<VALUE>

Many formats have one or more optional creation options that can be used to control particulars about the file created. For instance, the GeoTIFF driver supports creation options to control compression, and whether the file should be tiled.

May be repeated.

The creation options available vary by format driver, and some simple formats have no creation options at all. A list of options supported for a format can be listed with the *--formats* command line option but the documentation for the format is the definitive source of information on driver creation options. See *Raster drivers* format specific documentation for legal creation options for each format.

--if, --input-format <format>

Format/driver name to be attempted to open the input file(s). It is generally not necessary to specify it, but it can be used to skip automatic driver detection, when it fails to select the appropriate driver. This option can be repeated several times to specify several candidate drivers. Note that it does not force those drivers to open the dataset. In particular, some drivers have requirements on file extensions.

May be repeated.

--oo, --open-option <NAME>=<VALUE>

Dataset open option (format specific).

May be repeated.

--ot, --datatype, --output-data-type <OUTPUT-DATA-TYPE>

Output data type among `Byte`, `Int8`, `UInt16`, `Int16`, `UInt32`, `Int32`, `UInt64`, `Int64`, `CInt16`, `CInt32`, `Float32`, `Float64`, `CFloat32`, `CFloat64`.

-f, --of, --format, --output-format <OUTPUT-FORMAT>

Which output raster format to use. Allowed values may be given by `gdal --formats | grep raster | grep rw | sort`

--overwrite

Allow program to overwrite existing target file or dataset. Otherwise, by default, **gdal** errors out if the target file or dataset already exists.

Return status code

The program returns status code 0 in case of success, and non-zero in case of error (non-blocking errors emitted as warnings are considered as a successful execution).

Examples

Example 1: Unscale a scaled raster to a Float32 one

```
$ gdal raster unscale scaled_byte.tif unscaled_float32.tif --overwrite
```

5.1.3.48 gdal raster update

Added in version 3.12.

Synopsis

```
Usage: gdal raster update [OPTIONS] <INPUT> <OUTPUT>

Update the destination raster with the content of the input one.

Positional arguments:
  -i, --input <INPUT>                       Input raster datasets [required] [not␣
↪available in pipelines]
  -o, --output <OUTPUT>                     Output raster dataset [required]

Common Options:
  -h, --help                                Display help message and exit
  --json-usage                              Display usage as JSON document and exit
  --config <KEY>=<VALUE>                    Configuration option [may be repeated]
  -q, --quiet                               Quiet mode (no progress bar or warning␣
↪message) [not available in pipelines]

Options:

  --to, --transform-option <NAME>=<VALUE>    Transform option(s) [may be repeated]
  --et, --error-threshold <ERROR-THRESHOLD>  Error threshold
```

Description

gdal raster update can be used to update an existing output raster dataset with the pixel values of the input raster, doing reprojection if the input and output datasets do not have the same coordinate reference systems. The extent, size, resolution or coordinate reference system of the output dataset are not modified by this operation.

Overviews are updated by this command (using *gdal raster overview refresh*), unless `--no-update-overviews` is specified.

Starting with GDAL 3.13, **gdal raster update** can be used as a step of a pipeline, with the input dataset being the output of the previous step.

Program-Specific Options

--et, --error-threshold <ERROR-THRESHOLD>

Error threshold for transformation approximation, expressed as a number of input pixels. Defaults to 0.125 pixels unless the `RPC_DEM` transformer option is specified, in which case an exact transformer, i.e. `--error-threshold=0`, will be used.

--geometry <WKT_or_GeoJSON>

Geometry as a WKT or GeoJSON string of a polygon (or multipolygon) to which to restrict the update. If the input geometry is GeoJSON, its CRS is assumed to be WGS84, unless there is a CRS defined in the GeoJSON geometry or `--geometry-crs` is specified. If the input geometry is WKT, its CRS is assumed to be the one of the input dataset, unless `--geometry-crs` is specified. The X and Y axis are the "GIS friendly ones", that is X is longitude or easting, and Y is latitude or northing.

--geometry-crs <CRS>

CRS in which the coordinate values of `--geometry` are expressed. If not specified, it is assumed to be the CRS of the input dataset. The geometry will be reprojected from the geometry-crs to the CRS of the dataset being updated.

--no-update-overviews

Do not update existing overviews.

--to, --transform-option <NAME>=<VALUE>

Set a transformer option suitable to pass to *GDALCreateGenImgProjTransformer2()*. See *GDALCreateRPCTransformerV2()* for RPC specific options.

-r, --resampling <RESAMPLING>

Resampling method to use. Available methods are:

`nearest`: nearest neighbour resampling (default, fastest algorithm, worst interpolation quality).

`bilinear`: bilinear resampling.

`cubic`: cubic resampling.

`cubicspline`: cubic spline resampling.

`lanczos`: Lanczos windowed sinc resampling.

`average`: average resampling, computes the weighted average of all non-NODATA contributing pixels.

`rms` root mean square / quadratic mean of all non-NODATA contributing pixels

`mode`: mode resampling, selects the value which appears most often of all the sampled points. In the case of ties, the first value identified as the mode will be selected.

`max`: maximum resampling, selects the maximum value from all non-NODATA contributing pixels.

`min`: minimum resampling, selects the minimum value from all non-NODATA contributing pixels.

`med`: median resampling, selects the median value of all non-NODATA contributing pixels.

`q1`: first quartile resampling, selects the first quartile value of all non-NODATA contributing pixels.

`q3`: third quartile resampling, selects the third quartile value of all non-NODATA contributing pixels.

`sum`: compute the weighted sum of all non-NODATA contributing pixels

--wo, --warp-option <NAME>=<VALUE>

Set a warp option. The *GDALWarpOptions::papszWarpOptions* docs show all options. Multiple options may be listed.

Program-Specific Options

--if, --input-format <format>

Format/driver name to be attempted to open the input file(s). It is generally not necessary to specify it, but it can be used to skip automatic driver detection, when it fails to select the appropriate driver. This option can be repeated several times to specify several candidate drivers. Note that it does not force those drivers to open the dataset. In particular, some drivers have requirements on file extensions.

May be repeated.

--oo, --open-option <NAME>=<VALUE>

Dataset open option (format specific).

May be repeated.

Return status code

The program returns status code 0 in case of success, and non-zero in case of error (non-blocking errors emitted as warnings are considered as a successful execution).

Examples

Example 1: Update existing out.tif with content of in.tif using cubic interpolation

```
$ gdal raster update -r cubic in.tif out.tif
```

5.1.3.49 gdal raster viewshed

Added in version 3.11.

Synopsis

```
Usage: gdal raster viewshed [OPTIONS] <INPUT> <OUTPUT>

Compute the viewshed of a raster dataset.

```

Description

gdal raster viewshed creates a binary visibility raster from one band of the input raster elevation model (DEM). The output raster will be of type Byte. Using the `DEM` or `ground` values of `--mode` can also create a minimum visible height raster of type Float64.

It uses the method defined in [Wang2000] for a user defined point.

This subcommand is also available as a potential step of *gdal raster pipeline* (since GDAL 3.12)

Added in version 3.12.

GDALG output (on-the-fly / streamed dataset)

This program supports serializing the command line as a JSON file using the `GDALG` output format. The resulting file can then be opened as a raster dataset using the *GDALG: GDAL Streamed Algorithm* driver, and apply the specified pipeline in a on-the-fly / streamed way.

> **Note**
>
> However this algorithm is not natively streaming compatible. Consequently a temporary dataset will be generated, which may cause significant processing time at opening.

Program-Specific Options

-b, --band <band>

Select an input band containing the DEM data. Bands are numbered from 1. Only a single band can be used. Only the part of the raster within the specified maximum distance around the observer point is processed.

--curvature-coefficient <value>

Coefficient to consider the effect of the curvature and refraction. When calculating visibility between two points (i.e. Line Of Sight or Viewshed), The magnitude of this effect varies with atmospheric conditions and depends on the wavelength.

Different applications for calculating visibility use different interchangeable notation to describe this phenomena: Refraction Coefficient, Curvature Coefficient, and Sphere Diameter Factor. gdal_viewshed uses the Curvature Coefficient notation.

$$CurvCoeff = 1 - RefractionCoeff$$

Changes in air density curve the light downward causing an observer to see further and the earth to appear less curved, as if the sphere (earth) diameter is larger then it actually is. The ratio between that imaginary sphere diameter and the actual sphere diameter is given by the formula:

$$SphereDiameterFactor = 1/CurvCoeff = 1/(1 - RefractionCoeff)$$

For visible light, the standard atmospheric refraction coefficient that is generally used is 1/7. Thus the default value (since GDAL 3.4) for CurvCoeff that gdal_viewshed uses is 0.85714 (=~ 1-1/7) for Earth CRS. Starting with GDAL 3.6, for non-Earth CRS (those whole semi-major axis differs by more than 5% with the one of WGS 84), CurvCoeff default value is 1.0, to account for the no refraction use case.

The height of the DEM is corrected according to the following formula:

$$Height_{Corrected} = Height_{DEM} - CurvCoeff \frac{TargetDistance^2}{SphereDiameter}$$

Typical coefficient values are given in the table below (use Curvature Coeff value for the cc option)

Use Case	Refraction Coeff	**Curvature Coeff**	Sphere Diameter Factor
No Refraction	0	1	1
Visible Light	1/7	6/7 (=~0.85714)	7/6 (=~1.1666)
Radio Waves	0.25 ~ 0.325	0.75 ~ 0.675	1.33 ~ 1.48
Flat Earth	1	0	inf

--end-angle <value>

Added in version 3.12.

End angle for visibility. Measured clockwise from 0 North, in degree. (Not supported in cumulative mode)

-z, --height <HEIGHT>

Observer height

--high-pitch <value>

Added in version 3.12.

High angle for visibility. Measured up from 0 horizontal, in degree. Input values above the high pitch are marked out of range. Must be greater than '--low-pitch'. (Not supported in cumulative mode)

--invisible-value <value>

Pixel value to set for invisible areas. (Not supported in cumulative mode) Default: 0

--low-pitch <value>

Added in version 3.12.

Low angle for visibility. Measured up from 0 horizontal, in degree. Input cell values below the pitch are are clamped to be no lower than the intersection of the angle. Must be less than '--high-pitch'. (Not supported in cumulative mode)

--max-distance <value>

Maximum distance from observer to compute visibility. It is also used to clamp the extent of the output raster. (Not supported in cumulative mode)

--min-distance <value>

Added in version 3.12.

Minimum distance from observer to compute visibility. Must be less than '--max-distance' (Not supported in cumulative mode)

--mode normal|DEM|ground|cumulative

Sets what information the output contains.

- `normal` (the default) returns a raster of type Byte containing visible locations.
- `DEM` and `ground` return a raster of type Float64 containing the minimum target height for the target to be visible from the DEM surface or ground level respectively. That is to say, if the minimum target height for the target to be visible at a point is `h` and the value of the input raster at that point is `E`, for `DEM`, `E + h` will be the output value. For `ground`, `h` will be output value. Options `--target-height`, `--invisible-value` and `--visible-value` will be ignored.
- `cumulative` creates an eight bit raster the same size as the input raster where each cell represents the relative observability from a grid of observer points. See the *`--observer-spacing`* option.

-j, --num-threads <value>

Number of jobs to run at once. (only supported in cumulative mode). Default: 3

--observer-spacing <value>

Cell spacing between observers (only supported in cumulative mode). Default: 10

--out-of-range-value <value>

Pixel value to set for the cells that fall outside of the range specified by the observer location and the maximum distance. (Not supported in cumulative mode) Default: 0

--output-nodata <value>

The value to be set for the cells in the output raster that have no data.

> **Note**
>
> Currently, no special processing of input cells at a nodata value is done (which may result in erroneous results).

-p, --pos, --position <X,Y> or <X,Y,H>

The X,Y or X,Y,H(Height) position of the observer (in SRS units for X and Y, and in the height unit of the DEM for H). If the coordinate is outside of the raster, all space between the observer and the raster is assumed not to occlude visibility of the raster. (Not supported in cumulative mode.) If H is not specified, it defaults to 2.

--start-angle <value>

Added in version 3.12.

Start angle for visibility. Measured clockwise from 0 North, in degree. (Not supported in cumulative mode)

--target-height <value>

The height of the target above the DEM surface in the height unit of the DEM. Default: 0

--visible-value <value>

Pixel value to set for visible areas. (Not supported in cumulative mode) Default: 255

Added in version 3.13.

--sd-filename <value>

Filename of raster containing standard deviations of the input raster values. The raster always comes from band 1 and the size must match that of the input raster.

--maybe-visible-value <value>

Pixel value to set for visible areas. (Not supported in cumulative mode) Default: 255

Standard Options

--append

Append input raster as a new subdataset to an existing output file. Only works with drivers that support adding subdatasets such as *GTiff -- GeoTIFF File Format* and *GPKG -- GeoPackage raster* This also creates the output dataset if it does not exist yet.

--co, --creation-option <NAME>=<VALUE>

Many formats have one or more optional creation options that can be used to control particulars about the file created. For instance, the GeoTIFF driver supports creation options to control compression, and whether the file should be tiled.

May be repeated.

The creation options available vary by format driver, and some simple formats have no creation options at all. A list of options supported for a format can be listed with the *--formats* command line option but the documentation for the format is the definitive source of information on driver creation options. See *Raster drivers* format specific documentation for legal creation options for each format.

--if, --input-format <format>

Format/driver name to be attempted to open the input file(s). It is generally not necessary to specify it, but it can be used to skip automatic driver detection, when it fails to select the appropriate driver. This option can be repeated several times to specify several candidate drivers. Note that it does not force those drivers to open the dataset. In particular, some drivers have requirements on file extensions.

May be repeated.

--oo, --open-option <NAME>=<VALUE>

Dataset open option (format specific).

May be repeated.

-f, --of, --format, --output-format <OUTPUT-FORMAT>

Which output raster format to use. Allowed values may be given by `gdal --formats | grep raster | grep rw | sort`

--overwrite

Allow program to overwrite existing target file or dataset. Otherwise, by default, **gdal** errors out if the target file or dataset already exists.

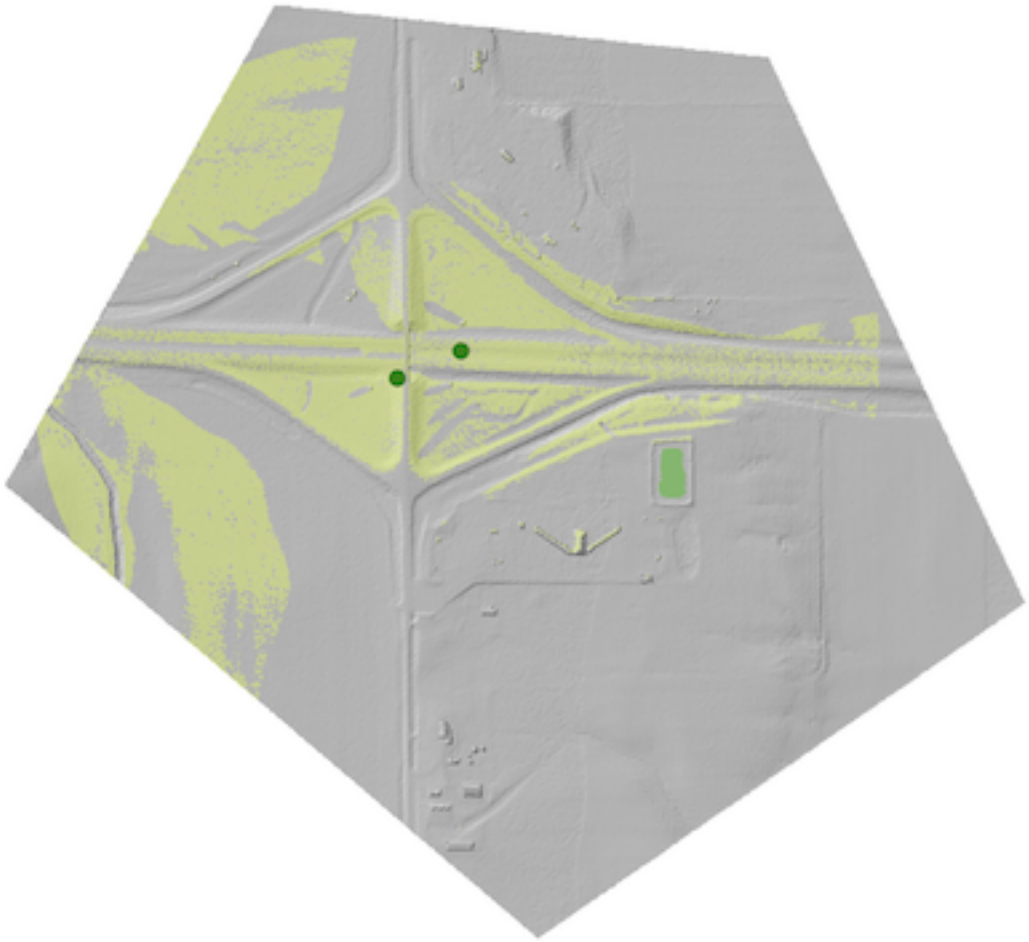
Return status code

The program returns status code 0 in case of success, and non-zero in case of error (non-blocking errors emitted as warnings are considered as a successful execution).

Examples

Example 1

Screenshot of 2 combined viewshed analysis, with the yellow pixels showing the area that is visible from the both observation locations (the green dots), while the small green area is only visible from one location.



Create a viewshed raster with a radius of 500 for a person standing at location (-10147017, 5108065).

```
gdal raster viewshed --max-distance=500 --pos=-10147017,5108065 source.tif destination.
↪tif
```

5.1.3.50 gdal raster pipeline write

Added in version 3.11.

Description

The `write` operation is for use in a *gdal pipeline* only, and writes a raster dataset. This is the last step of a pipeline.

To write a temporary dataset in the middle of a pipeline, use *gdal raster materialize*.

Synopsis

```
* write [OPTIONS] <OUTPUT>
--------------------------

Write a raster dataset.

Positional arguments:
  -o, --output <OUTPUT>                                Output raster dataset [required]

Options:
  -f, --of, --format, --output-format <OUTPUT-FORMAT>  Output format ("GDALG" allowed)
  --co, --creation-option <KEY>=<VALUE>                Creation option [may be repeated]
  --overwrite                                          Whether overwriting existing␣
↪output dataset is allowed
                                                       Mutually exclusive with --append
  --append                                             Append as a subdataset to␣
↪existing output
                                                       Mutually exclusive with --
↪overwrite
```

Standard Options

-f, --of, --format, --output-format <OUTPUT-FORMAT>

Which output raster format to use. Allowed values may be given by `gdal --formats | grep raster | grep rw | sort`

--co, --creation-option <NAME>=<VALUE>

Many formats have one or more optional creation options that can be used to control particulars about the file created. For instance, the GeoTIFF driver supports creation options to control compression, and whether the file should be tiled.

May be repeated.

The creation options available vary by format driver, and some simple formats have no creation options at all. A list of options supported for a format can be listed with the *--formats* command line option but the documentation for the format is the definitive source of information on driver creation options. See *Raster drivers* format specific documentation for legal creation options for each format.

--overwrite

Allow program to overwrite existing target file or dataset. Otherwise, by default, **gdal** errors out if the target file or dataset already exists.

--append

Append input raster as a new subdataset to an existing output file. Only works with drivers that support adding subdatasets such as *GTiff -- GeoTIFF File Format* and *GPKG -- GeoPackage raster* This also creates the output dataset if it does not exist yet.

Examples

Example 1: Write a GeoTIFF file

```
$ gdal raster pipeline ... [other commands here] ... ! write out.tif --overwrite
```

5.1.3.51 gdal raster zonal-stats

Added in version 3.12.

Synopsis

```
Usage: gdal raster zonal-stats [OPTIONS] <INPUT> <OUTPUT>

Calculate raster zonal statistics

Positional arguments:
  -i, --input <INPUT>                                    Input raster datasets [required]␣
↪[not available in pipelines]
  -o, --output <OUTPUT>                                  Output vector dataset [required]␣
↪[not available in pipelines]

Common Options:
  -h, --help                                             Display help message and exit
  --json-usage                                           Display usage as JSON document␣
↪and exit
  --config <KEY>=<VALUE>                                 Configuration option [may be␣
↪repeated]
  -q, --quiet                                            Quiet mode (no progress bar or␣
↪warning message) [not available in pipelines]

Options:
  -f, --of, --format, --output-format <OUTPUT-FORMAT>  Output format ("GDALG" allowed)␣
↪[not available in pipelines]
  --co, --creation-option <KEY>=<VALUE>                  Creation option [may be repeated]␣

↪') [not available in pipelines]
                                                          Mutually exclusive with --append
```

Description

gdal raster zonal-stats computes raster zonal statistics -- a summary of pixel values within zones specified either polygon features or a categorical raster.

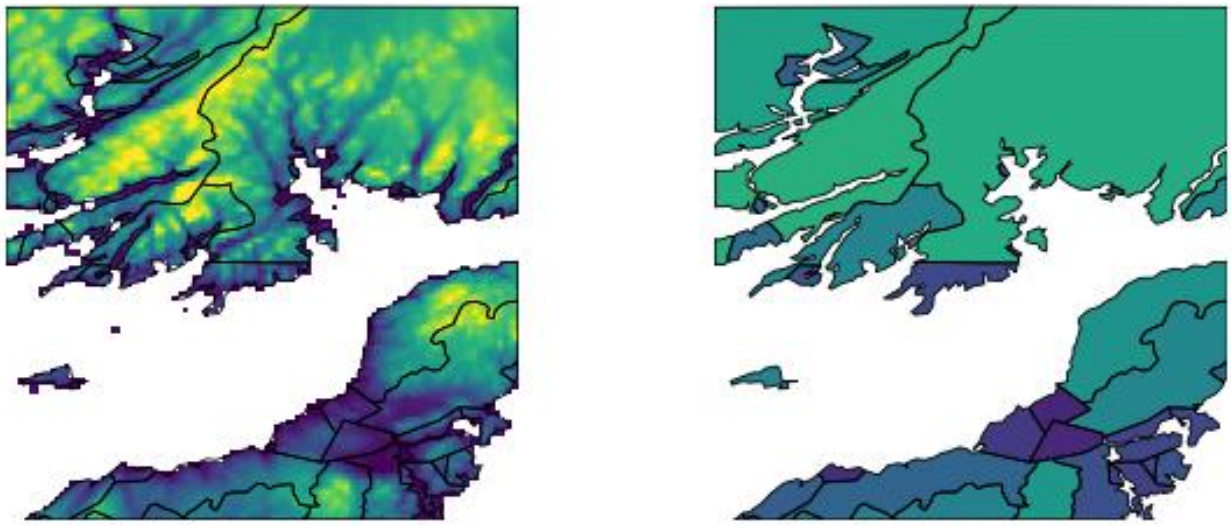

Fig. 4: Mean elevation calculated for each polygon from an elevation raster.

A weighting raster may be provided in addition to the source raster, allowing calculation of statistics such as population-weighted mean weather conditions.

All inputs should be provided in the same spatial reference system. If input rasters use different resolutions they will be resampled to a consistent resolution using average resampling. However, no reprojection is performed.

Pixel inclusion and weighting

When zones are defined using polygons, three methods are available for determining which pixels to include in the calculation. By default, the geometries are rasterized using default parameters, and pixels included in the rasterization are used in the calculation with equal weighting. By using `--pixels all-touched`, all pixels touched by the polygon are used in the calculation, again with equal weighting. If using `--pixels fractional`, the fraction of each pixel that is covered by the polygon is computed, and pixels are weighted according to this fraction. This option requires GDAL be built against version 3.14 or later of the GEOS library.

Supported stats

Name	Description
center_x	Array with cell center x-coordinate for each cell that intersects the polygon. Each cell center may or may not be inside the polygon.
center_y	Array with cell center y-coordinate for each cell that intersects the polygon. Each cell center may or may not be inside the polygon.
count	Sum of all cell coverage fractions.
coverage	Array with coverage fraction of each cell that intersects the polygon
frac	Fraction of covered cells that are occupied by each distinct raster value, as provided by `unique`.
max	Maximum value of cells that intersect the polygon, not taking coverage fractions or weighting raster values into account.
max_center_	Cell center x-coordinate for the cell containing the maximum value intersected by the polygon. The center of this cell may or may not be inside the polygon.
max_center_	Cell center y-coordinate for the cell containing the maximum value intersected by the polygon. The center of this cell may or may not be inside the polygon.
mean	Mean value of cells that intersect the polygon, weighted by the percent of each cell that is covered.
min	Minimum value of cells that intersect the polygon, not taking coverage fractions or weighting raster values into account.
min_center_	Cell center x-coordinate for the cell containing the minimum value intersected by the polygon. The center of this cell may or may not be inside the polygon.
min_center_	Cell center y-coordinate for the cell containing the minimum value intersected by the polygon. The center of this cell may or may not be inside the polygon.
minority	The raster value occupying the least number of cells, taking into account cell coverage fractions but not weighting raster values.
mode	The raster value occupying the greatest number of cells, taking into account cell coverage fractions but not weighting raster values.
stdev	Population standard deviation of cell values that intersect the polygon, taking into account coverage fraction.
sum	Sum of values of raster cells that intersect the polygon, with each raster value weighted by its coverage fraction.
unique	Array of unique raster values for cells that intersect the polygon
values	Array of raster values for each cell that intersects the polygon
variance	Population variance of cell values that intersect the polygon, taking into account coverage fraction.
variety	The number of distinct raster values in cells wholly or partially covered by the polygon.
weighted_fr	Fraction of covered cells that are occupied by each distinct raster value, weighted by the value of a second weighting raster. Order corresponds to values returned by `unique`.
weighted_m	Mean value of cells that intersect the polygon, weighted by the product over the coverage fraction and the weighting raster.
weighted_st	Weighted version of `stdev`.
weighted_va	Weighted version of `variance`
weights	Array of weight values for each cell that intersects the polygon

This algorithm can be part of a *gdal pipeline*.

Program-Specific Options

--band, -b <BAND>

Input band(s) to be processed.

--chunk-size <MEMORY>

Defines the maximum size of raster chunks to read. May be expressed as either an amount of memory (500 MB, 2 GB, etc.) or as a percentage of available RAM (e.g. 10%).

--include-field <INCLUDE-FIELD>

Specifies one or more fields from the zones to be copied to the output. Only available when vector zones are used. Since GDAL 3.13, the special values "ALL" and "NONE" can be used.

--include-geom

Include the zone geometry in the output feature. Only available when vector zones are used.

Added in version 3.13.

--pixels <PIXELS>

Method to determine which pixels should be included in the calculation: `default`, `all-touched`, or `fractional`.

--stat <STAT>

Specifies one or more of the *Supported stats* to compute for each zone.

--strategy <STRATEGY>

Specifies the the processing strategy (`raster` or `feature`), when vector zones are used. In the default strategy (`--strategy feature`), GDAL will iterate over the features in the zone dataset, read the corresponding pixels from the raster, and write the statistics for that feature. This avoids the need to read the entire feature dataset into memory at once, but may cause the same pixels to be read multiple times if the polygon features are large or not ordered spatially. If `--strategy raster` is used, GDAL will iterate over chunks of the raster dataset, find corresponding polygon zones, and update the statistics for those features. (The size of the raster chunks can be controlled using :option:`--chunk-size`.) This ensures that raster pixels are only read once, but may cause the same features to be processed multiple times.

--weights <WEIGHTS>

Optional path to a dataset to use for weighting.

--weights-band <WEIGHTS-BAND>

Specifies the raster band from which weights can be read.

--zones <ZONES>

The path to a dataset that defines the zones. If the dataset has more than 1 raster band or feature layer, *--zones-band* or *--zones-layer* must be specified.

--zones-band <ZONES-BAND>

Specifies the raster band from which zones can be read.

--zones-layer <ZONES-LAYER>

Specifies the feature layer from which zones can be read.

Standard Options

--append

Whether appending features to existing layer(s) is allowed. This also creates the output dataset if it does not exist yet.

--co, --creation-option <NAME>=<VALUE>

Many formats have one or more optional dataset creation options that can be used to control particulars about the file created. For instance, the GeoPackage driver supports creation options to control the version.

May be repeated.

The dataset creation options available vary by format driver, and some simple formats have no creation options at all. A list of options supported for a format can be listed with the *--formats* command line option but the documentation for the format is the definitive source of information on driver creation options. See *Vector drivers* format specific documentation for legal creation options for each format.

Note that dataset creation options are different from layer creation options.

--if, --input-format <format>

Format/driver name to be attempted to open the input file(s). It is generally not necessary to specify it, but it can be used to skip automatic driver detection, when it fails to select the appropriate driver. This option can be repeated several times to specify several candidate drivers. Note that it does not force those drivers to open the dataset. In particular, some drivers have requirements on file extensions.

May be repeated.

--lco, --layer-creation-option <NAME>=<VALUE>

Many formats have one or more optional layer creation options that can be used to control particulars about the layer created. For instance, the GeoPackage driver supports layer creation options to control the feature identifier or geometry column name, setting the identifier or description, etc.

May be repeated.

The layer creation options available vary by format driver, and some simple formats have no layer creation options at all. A list of options supported for a format can be listed with the *--formats* command line option but the documentation for the format is the definitive source of information on driver creation options. See *Vector drivers* format specific documentation for legal creation options for each format.

Note that layer creation options are different from dataset creation options.

--oo, --open-option <NAME>=<VALUE>

Dataset open option (format specific).

May be repeated.

-f, --of, --format, --output-format <OUTPUT-FORMAT>

Which output vector format to use. Allowed values may be given by `gdal --formats | grep vector | grep rw | sort`

--output-layer <NAME>

Specifies the name of the layer to which features will be written. If not specified, output layer names will be the same as input layer names.

--output-open-option, --output-oo <NAME>=<VALUE>

Added in version 3.12.

Dataset open option for output dataset (format specific).

May be repeated.

--overwrite

Allow program to overwrite existing target file or dataset. Otherwise, by default, **gdal** errors out if the target file or dataset already exists.

--overwrite-layer

Whether overwriting the existing output vector layer is allowed.

--skip-errors

Added in version 3.12.

Whether failures to write feature(s) should be ignored. Note that this option sets the size of the transaction unit to one feature at a time, which may cause severe slowdown when inserting into databases.

--update

Whether to open an existing output dataset in update mode.

--upsert

Added in version 3.12.

Variant of *--append* where the *OGRLayer::UpsertFeature()* operation is used to insert or update features instead of appending with *OGRLayer::CreateFeature()*.

This is currently implemented only in a few drivers: *GPKG -- GeoPackage vector*, *Elasticsearch: Geographically Encoded Objects for Elasticsearch* and *MongoDBv3* (drivers that implement upsert expose the *GDAL_DCAP_UPSERT* capability).

The upsert operation uses the FID of the input feature, when it is set (and the FID column name is not the empty string), as the key to update existing features. It is crucial to make sure that the FID in the source and target layers are consistent.

For the GPKG driver, it is also possible to upsert features whose FID is unset or non-significant (the `--unset-fid` option of *gdal vector edit* can be used to ignore the FID from the source feature), when there is a UNIQUE column that is not the integer primary key.

Return status code

The program returns status code 0 in case of success, and non-zero in case of error (non-blocking errors emitted as warnings are considered as a successful execution).

Examples

Example 1: Summarize mean elevation within 200m of points of interest

Using a nested pipeline for the zone dataset

```
  gdal pipeline read dem.tif ! \
      zonal-stats \
        --zones [ read points.geojson ! buffer 200 ] \
        --stat mean ! \
      write \
        --output-format CSV \
        --output /vsistdout/

or, using the zone vector dataset as the piped dataset using the ``_PIPE_`` placeholder␣
↪dataset name:
```

```
gdal pipeline read points.geojson ! \
    buffer 200 ! \
    zonal-stats \
      --input dem.tif
      --zones _PIPE_ \
      --stat mean ! \
    write \
      --output-format CSV \
      --output /vsistdout/
```

Example 2: Create a layer with the highest points in each watershed

```
gdal pipeline read dem.tif !
    zonal-stats \
```

(continues on next page)

(continued from previous page)

```
      --zones watersheds.shp \
      --stat max_center_x \
      --stat max_center_y ! \
    make-point \
      --x max_center_x \
      --y max_center_y \
      --output-crs EPSG:4326 ! \
    write out.geojson
```

5.1.4 Vector commands

5.1.4.1 gdal vector

Added in version 3.11.

Synopsis

```
Usage: gdal vector <SUBCOMMAND> [OPTIONS]
where <SUBCOMMAND> is one of:
  - buffer:              Compute a buffer around geometries of a vector dataset.
  - check-coverage:      Check a polygon coverage for validity
  - check-geometry:      Check a dataset for invalid geometries
  - clean-coverage:      Alter polygon boundaries to make shared edges identical,␣
↪removing gaps and overlaps
  - clip:                Clip a vector dataset.
  - combine:             Combine features into collections
  - concat:              Concatenate vector datasets.
  - concave-hull:        Compute the concave hull of geometries of a vector dataset.
  - convert:             Convert a vector dataset.
  - convex-hull:         Compute the convex hull of geometries of a vector dataset.
  - create:              Create a vector dataset.
  - dissolve:            Dissolves multipart features
  - edit:                Edit metadata of a vector dataset.
  - explode-collections: Explode geometries of type collection of a vector dataset.
  - export-schema:       Export the OGR_SCHEMA from a vector dataset.
  - filter:              Filter a vector dataset.
  - grid:                Create a regular grid from scattered points.
  - index:               Create a vector index of vector datasets.
  - info:                Return information on a vector dataset.
  - layer-algebra:       Perform algebraic operation between 2 layers.
  - make-point:          Create point geometries from attribute fields
  - make-valid:          Fix validity of geometries of a vector dataset.
  - partition:           Partition a vector dataset into multiple files.
  - pipeline:            Process a vector dataset applying several steps.
  - rasterize:           Burns vector geometries into a raster.
  - rename-layer:        Rename layer(s) of a vector dataset.
  - reproject:           Reproject a vector dataset.
  - segmentize:          Segmentize geometries of a vector dataset.
  - select:              Select a subset of fields from a vector dataset.
  - set-field-type:      Modify the type of a field of a vector dataset.
  - set-geom-type:       Modify the geometry type of a vector dataset.
  - simplify:            Simplify geometries of a vector dataset.
```

(continues on next page)

(continued from previous page)

```
  - simplify-coverage:   Simplify shared boundaries of a polygonal vector dataset.
  - sort:                Spatially order the features in a layer
  - sql:                 Apply SQL statement(s) to a dataset.
  - swap-xy:             Swap X and Y coordinates of geometries of a vector dataset.
  - update:              Update an existing vector dataset with an input vector dataset.

Common Options:
  -h, --help              Display help message and exit
  --json-usage            Display usage as JSON document and exit
  --config <KEY>=<VALUE>  Configuration option [may be repeated]

Options:
  --drivers               Display vector driver list as JSON document and exit
```

Available sub-commands

- *gdal vector clip*
- *gdal vector concat*
- *gdal vector convert*
- *gdal vector create*
- *gdal vector edit*
- *gdal vector filter*
- *gdal vector index*
- *gdal vector info*
- *gdal vector export-schema*
- *gdal vector layer-algebra*
- *gdal vector partition*
- *gdal vector pipeline*
- *gdal vector rasterize*
- *gdal vector rename-layer*
- *gdal vector reproject*
- *gdal vector select*
- *gdal vector set-field-type*
- *gdal vector set-geom-type*
- *gdal vector sql*
- *gdal vector update*

Examples

Example 1: Getting information on the file poly.gpkg (with text output)

```
$ gdal vector info poly.gpkg
```

Example 2: Converting file poly.gpkg to Esri File Geodatabase

```
$ gdal vector convert --format=OpenFileGDB poly.gpkg poly.gdb
```

Example 3: Check if the vector Parquet driver is installed

Bash

PowerShell

```
gdal vector --formats | grep Parquet
```

```
gdal vector --formats | Select-String "Parquet"
```

5.1.4.2 gdal vector buffer

Added in version 3.12.

Synopsis

```
Usage: gdal vector buffer [OPTIONS] <INPUT> <OUTPUT> <DISTANCE>

Compute a buffer around geometries of a vector dataset.

Positional arguments:
  -i, --input <INPUT>                                    Input vector datasets [required]␣
↪[not available in pipelines]
  -o, --output <OUTPUT>                                  Output vector dataset [required]␣
↪[not available in pipelines]
  --distance <DISTANCE>                                  Distance to which to extend the␣
↪geometry. [required]

Common Options:
  -h, --help                                             Display help message and exit
  --json-usage                                           Display usage as JSON document␣
↪and exit
  --config <KEY>=<VALUE>                                 Configuration option [may be␣
↪repeated]
  -q, --quiet                                            Quiet mode (no progress bar or␣
↪warning message) [not available in pipelines]

Options:

↪') [not available in pipelines]
                                                       Mutually exclusive with --append
```

Description

gdal vector buffer computes a POLYGON or MULTIPOLYGON that represents all points whose distance from a geometry/geography is less than or equal to a given distance. A negative distance shrinks the geometry rather than expanding it. A negative distance may shrink a polygon completely, in which case POLYGON EMPTY is returned. For points and lines negative distances always return empty results.

See the PostGIS ST_Buffer docs for additional graphical illustrations of the effect of the different parameters.

The output dataset is always written as `MULTIPOLYGON`, even when the input contains only simple `POLYGON` geometries. Note that negative buffer distances may also produce `MULTIPOLYGON` results.

Using a buffer distance of 0 can sometimes repair invalid geometries, but the recommended approach is to use **gdal**

vector make-valid for reliable geometry validation and repair.

This command can also be used as a step of *gdal vector pipeline*.

GDALG output (on-the-fly / streamed dataset)

This program supports serializing the command line as a JSON file using the `GDALG` output format. The resulting file can then be opened as a vector dataset using the *GDALG: GDAL Streamed Algorithm* driver, and apply the specified pipeline in a on-the-fly / streamed way.

> **Note**
>
> This command requires a GDAL build against the GEOS library.

Program-Specific Options

--distance `<DISTANCE>`

Radius of the buffer around the input geometry. The unit of the distance is in georeferenced units of the source layer.

--endcap-style `round|flat|square`

Specifies the end cap style of the generated buffer. Default is `round`.

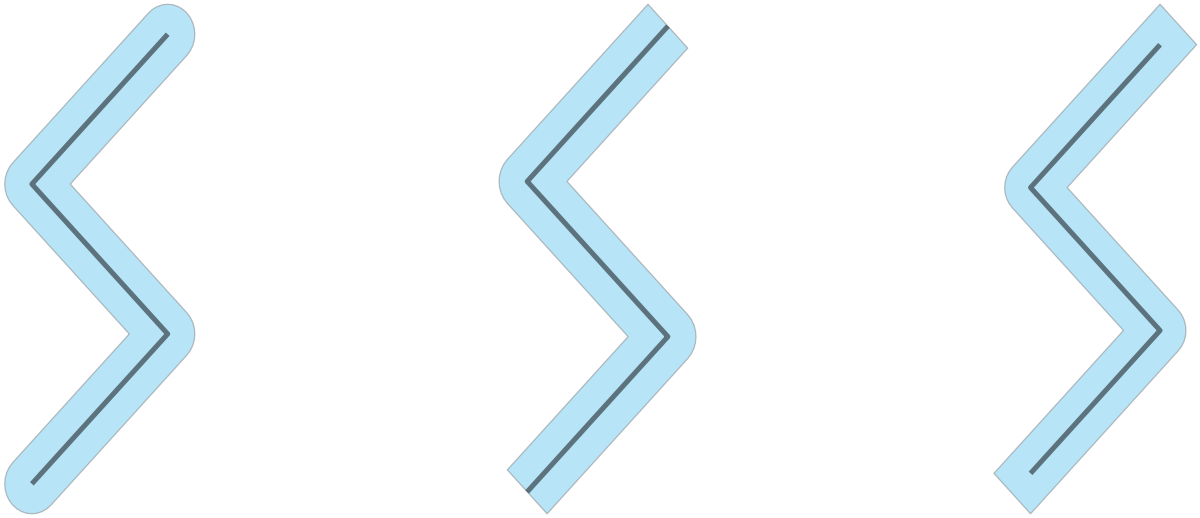

Fig. 5: Buffered lines with `endcap-style=round`, `endcap-style=flat` and `endcap-style=square`

--join-style `round|mitre|bevel`

Sets the join style for outside (reflex) corners between line segments. Default is `round`.

--input-layer `<NAME>`

Specifies one or more layer names to read and process. By default, all layers will be read and processed. To read and write all layers but only process a subset, use *`--active-layer`*.

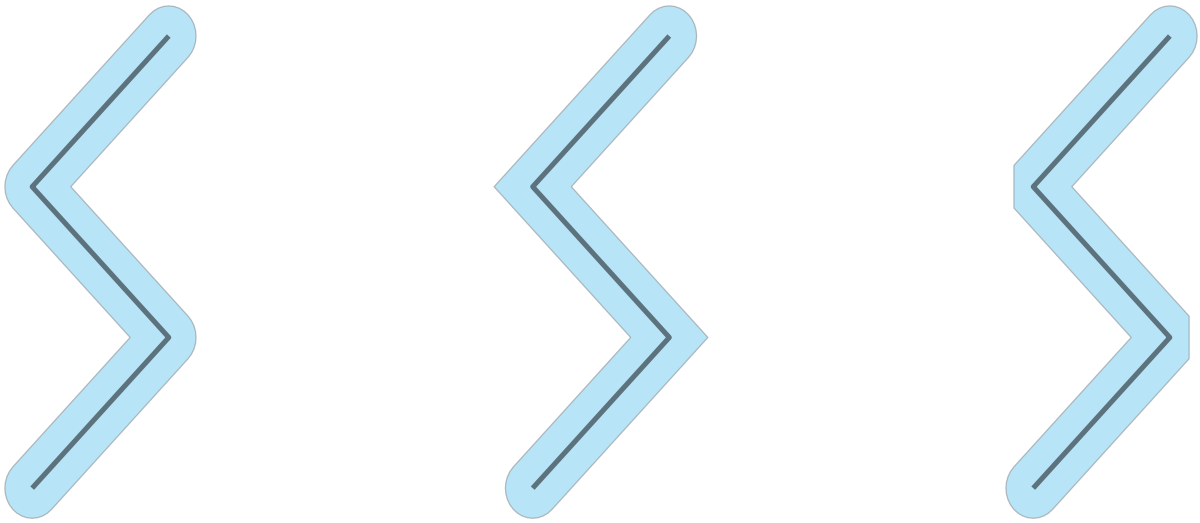

Fig. 6: Buffered lines with `join-style=round`, `join-style=mitre` and `join-style=bevel`

--mitre-limit <MITRE-LIMIT>

Sets the limit on the mitre ratio used for very sharp corners. This option only applies when `join-style=mitre` is used.

Default is 5.

The mitre ratio is the ratio of the distance from the corner to the end of the mitred offset corner. When two line segments meet at a sharp angle, a miter join will extend far beyond the original geometry. (and in the extreme case will be infinitely far.) To prevent unreasonable geometry, the mitre limit allows controlling the maximum length of the join corner. Corners with a ratio which exceed the limit will be beveled.

--output-layer <NAME>

Name of the layer to which output should be written. If not specified, the output layer will have the same name as the input layer.

--quadrant-segments <QUADRANT-SEGMENTS>

Sets the number of line segments used to approximate an angle fillet in round joins.

This determines the maximum error in the approximation to the true buffer curve. The default value of 8 gives less than 2% max error in the buffer distance. For a max error of < 1%, use QS = 12. For a max error of < 0.1%, use QS = 18. The error is always less than the buffer distance (in other words, the computed buffer curve is always inside the true curve).

--side `both|left|right`

Sets whether the computed buffer should be single-sided or on both sides (default).

`left` indicates that the buffer is generated on the left-hand side of the line, and `right` indicates that the buffer is generated on the right-hand side of the line, determined by the order of the line's vertices (i.e., the direction in which the line is drawn).

Single-side buffering is only applicable to LINESTRING geometry and does not affect POINT or POLYGON geometries, and the end cap style is forced to square.

Fig. 7: Lines with a `distance=2` buffer, and `mitre-limit=5` on the left, and `mitre-limit=1` on the right

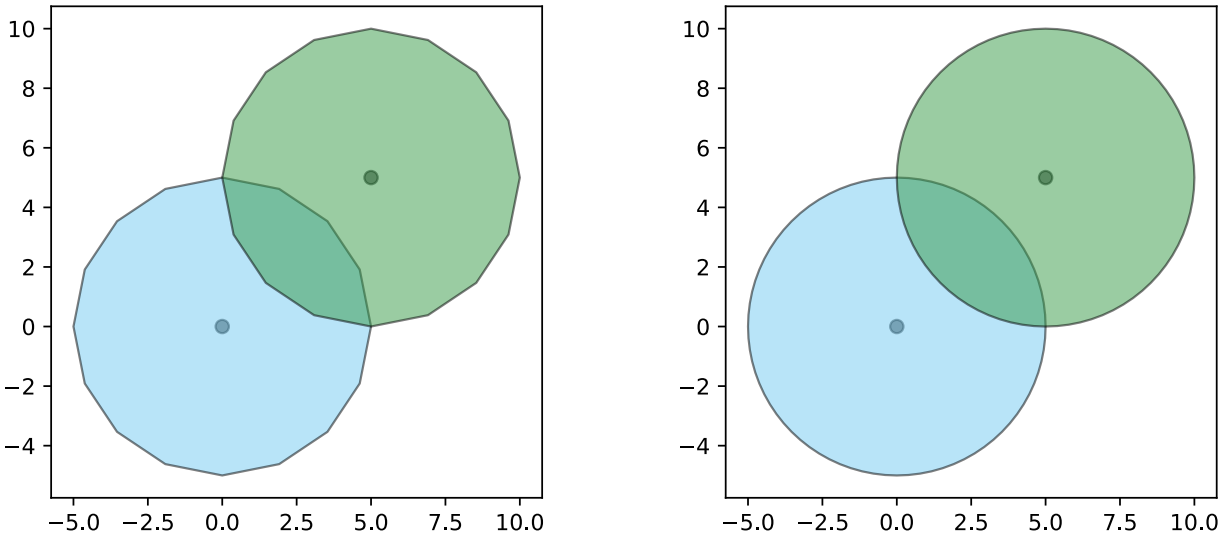

Fig. 8: Buffered points with `quadrant-segments=4` and `quadrant-segments=20`

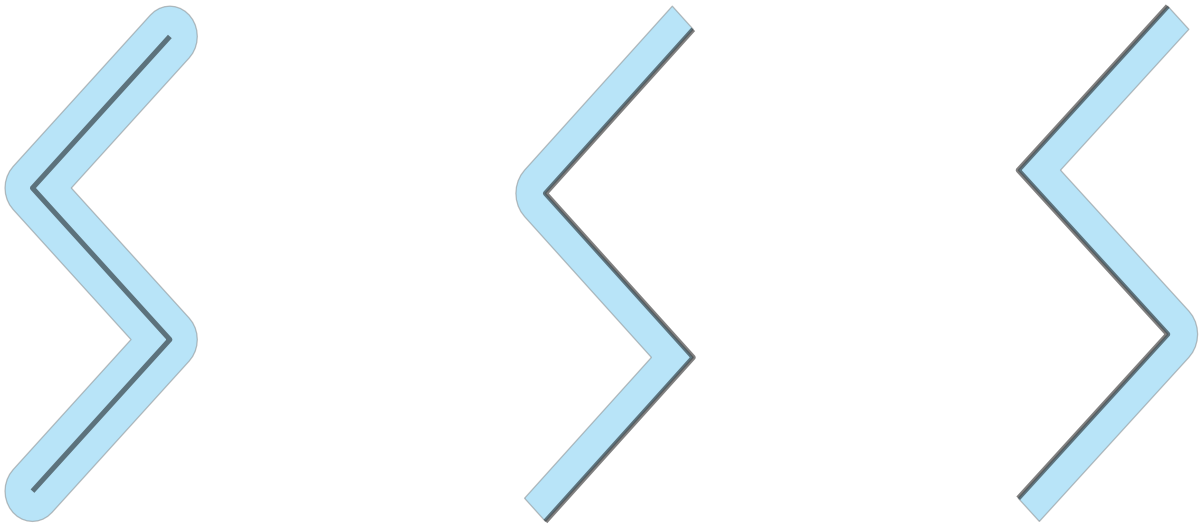

Fig. 9: Buffered lines with `side=both`, `side=left` and `side=right`

Standard Options

--append

Whether appending features to existing layer(s) is allowed. This also creates the output dataset if it does not exist yet.

--active-layer <ACTIVE-LAYER>

Set the active layer. When it is specified, only the layer specified by its name will be subject to the processing. Other layers will be not modified. If this option is not specified, all layers will be subject to the processing.

--active-geometry <ACTIVE-GEOMETRY>

Set the active geometry field from its name. When it is specified, only the specified geometry field will be subject to the processing. Other geometry fields will be not modified. If this option is not specified, all geometry fields will be subject to the processing. This option can be combined together with *--active-layer*.

--co, --creation-option <NAME>=<VALUE>

Many formats have one or more optional dataset creation options that can be used to control particulars about the file created. For instance, the GeoPackage driver supports creation options to control the version.

May be repeated.

The dataset creation options available vary by format driver, and some simple formats have no creation options at all. A list of options supported for a format can be listed with the *--formats* command line option but the documentation for the format is the definitive source of information on driver creation options. See *Vector drivers* format specific documentation for legal creation options for each format.

Note that dataset creation options are different from layer creation options.

--if, --input-format <format>

Format/driver name to be attempted to open the input file(s). It is generally not necessary to specify it, but it can be used to skip automatic driver detection, when it fails to select the appropriate driver. This option can be repeated several times to specify several candidate drivers. Note that it does not force those drivers to open the dataset. In particular, some drivers have requirements on file extensions.

May be repeated.

--lco, --layer-creation-option <NAME>=<VALUE>

Many formats have one or more optional layer creation options that can be used to control particulars about the layer created. For instance, the GeoPackage driver supports layer creation options to control the feature identifier or geometry column name, setting the identifier or description, etc.

May be repeated.

The layer creation options available vary by format driver, and some simple formats have no layer creation options at all. A list of options supported for a format can be listed with the *--formats* command line option but the documentation for the format is the definitive source of information on driver creation options. See *Vector drivers* format specific documentation for legal creation options for each format.

Note that layer creation options are different from dataset creation options.

--oo, --open-option <NAME>=<VALUE>

Dataset open option (format specific).

May be repeated.

-f, --of, --format, --output-format <OUTPUT-FORMAT>

Which output vector format to use. Allowed values may be given by `gdal --formats | grep vector | grep rw | sort`

--output-open-option, --output-oo <NAME>=<VALUE>

Added in version 3.12.

Dataset open option for output dataset (format specific).

May be repeated.

--overwrite

Allow program to overwrite existing target file or dataset. Otherwise, by default, **gdal** errors out if the target file or dataset already exists.

--overwrite-layer

Whether overwriting the existing output vector layer is allowed.

--skip-errors

Added in version 3.12.

Whether failures to write feature(s) should be ignored. Note that this option sets the size of the transaction unit to one feature at a time, which may cause severe slowdown when inserting into databases.

--update

Whether to open an existing output dataset in update mode.

--upsert

Added in version 3.12.

Variant of *--append* where the *OGRLayer::UpsertFeature()* operation is used to insert or update features instead of appending with *OGRLayer::CreateFeature()*.

This is currently implemented only in a few drivers: *GPKG -- GeoPackage vector*, *Elasticsearch: Geographically Encoded Objects for Elasticsearch* and *MongoDBv3* (drivers that implement upsert expose the *GDAL_DCAP_UPSERT* capability).

The upsert operation uses the FID of the input feature, when it is set (and the FID column name is not the empty string), as the key to update existing features. It is crucial to make sure that the FID in the source and target layers are consistent.

For the GPKG driver, it is also possible to upsert features whose FID is unset or non-significant (the `--unset-fid` option of *gdal vector edit* can be used to ignore the FID from the source feature), when there is a UNIQUE column that is not the integer primary key.

Return status code

The program returns status code 0 in case of success, and non-zero in case of error (non-blocking errors emitted as warnings are considered as a successful execution).

Examples

Example 1: Compute a buffer of one km around input geometries (assuming the CRS is in meters)

```
$ gdal vector buffer --distance=1000 in.gpkg out.gpkg --overwrite
```

Example 2: Buffer a point dataset with 20 segments per quadrant (instead of default 8) to better approximate a circle

```
$ gdal vector buffer --distance=20 --quadrant-segments=20 points.gpkg point_buffers.gpkg
```

Example 3: Buffer lines to the left using join and end cap styles

```
$ gdal vector buffer --distance=10 --endcap-style=flat --side=left --join-style=mitre --
↪mitre-limit=2 lines.gpkg lines-buffer-endcap.gpkg
```

Example 4: Clip and buffer a zipped line dataset as part of a pipeline

Bash

PowerShell

```
gdal vector pipeline \
! read "/vsizip/lines.zip" \
! clip --bbox 647903,6863599,648703,6864399 \
! buffer --distance=5 \
! write line-buffer.gpkg --overwrite
```

```
gdal vector pipeline `
! read "/vsizip/lines.zip" `
! clip --bbox 647903,6863599,648703,6864399 `
! buffer --distance=5 `
! write line-buffer.gpkg --overwrite
```

5.1.4.3 gdal vector check-coverage

Added in version 3.12.

Synopsis

```
Usage: gdal vector check-coverage [OPTIONS] <INPUT> <OUTPUT>
```

(continues on next page)

(continued from previous page)

```
Check a polygon coverage for validity

Positional arguments:

```

Description

gdal vector check-coverage checks whether a polygon dataset forms a valid coverage, meaning:

- no polygons overlap
- all shared edges have nodes at the same locations
- any gaps between polygons are larger than a specified width

For each polygon not satisfying these criteria, a linear feature with the geometry of the invalid edge is output. If the coverage is valid, the output dataset will be empty unless `--include-valid` is used.

It is assumed that the individual polygons are themselves valid according to the OGC Simple Features standard. This can be checked by *gdal vector check-geometry*.

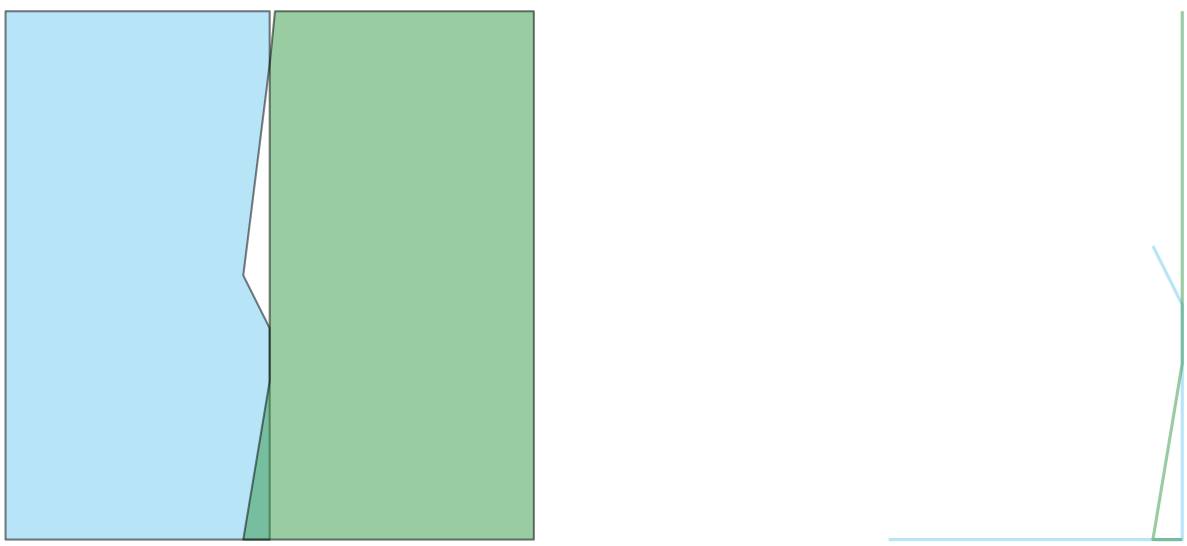

Fig. 10: Polygon dataset (left) and locations of invalid coverage edges (right).

> **Note**
>
> This command requires a GDAL build against the GEOS library (version 3.12 or greater).

GDALG output (on-the-fly / streamed dataset)

This program supports serializing the command line as a JSON file using the `GDALG` output format. The resulting file can then be opened as a vector dataset using the *GDALG: GDAL Streamed Algorithm* driver, and apply the specified pipeline in a on-the-fly / streamed way.

> **Note**
>
> However this algorithm is not natively streaming compatible. Consequently a in-memory temporary dataset will be generated, which may cause significant processing time at opening.

Program-Specific Options

--geometry-field

Specify the name of the geometry field to test, for layers having multiple geometry fields. By default the first geometry field will be used.

--include-valid

Include features for valid geometries in the output, maintaining 1:1 correspondence between input and output features. The geometry of valid features will be an empty geometry.

--input-layer

Specifies the name of the layer to process. By default, all layers will be processed.

--output-layer

Specifies the name of the layer to which features will be written. If not specified and there is a single input layer, the name "invalid_edge" will be used. If not specified and there are multiple input layers, features for each input layer will be written to a separate output layer in the format "invalid_edge_{INPUT_LAYER}".

--maximum-gap-width <MAXIMUM-GAP-WIDTH>

Defines the largest area that should be considered a gap.

Standard Options

--append

Whether appending features to existing layer(s) is allowed. This also creates the output dataset if it does not exist yet.

--co, --creation-option <NAME>=<VALUE>

Many formats have one or more optional dataset creation options that can be used to control particulars about the file created. For instance, the GeoPackage driver supports creation options to control the version.

May be repeated.

The dataset creation options available vary by format driver, and some simple formats have no creation options at all. A list of options supported for a format can be listed with the *--formats* command line option but the documentation for the format is the definitive source of information on driver creation options. See *Vector drivers* format specific documentation for legal creation options for each format.

Note that dataset creation options are different from layer creation options.

--if, --input-format <format>

Format/driver name to be attempted to open the input file(s). It is generally not necessary to specify it, but it can be used to skip automatic driver detection, when it fails to select the appropriate driver. This option can be repeated several times to specify several candidate drivers. Note that it does not force those drivers to open the dataset. In particular, some drivers have requirements on file extensions.

May be repeated.

--lco, --layer-creation-option <NAME>=<VALUE>

Many formats have one or more optional layer creation options that can be used to control particulars about the

layer created. For instance, the GeoPackage driver supports layer creation options to control the feature identifier or geometry column name, setting the identifier or description, etc.

May be repeated.

The layer creation options available vary by format driver, and some simple formats have no layer creation options at all. A list of options supported for a format can be listed with the *--formats* command line option but the documentation for the format is the definitive source of information on driver creation options. See *Vector drivers* format specific documentation for legal creation options for each format.

Note that layer creation options are different from dataset creation options.

--no-create-empty-layers

Added in version 3.13.

Avoid creating layers to which no features will be written.

--oo, --open-option <NAME>=<VALUE>

Dataset open option (format specific).

May be repeated.

-f, --of, --format, --output-format <OUTPUT-FORMAT>

Which output vector format to use. Allowed values may be given by `gdal --formats | grep vector | grep rw | sort`

--output-open-option, --output-oo <NAME>=<VALUE>

Added in version 3.12.

Dataset open option for output dataset (format specific).

May be repeated.

--overwrite

Allow program to overwrite existing target file or dataset. Otherwise, by default, **gdal** errors out if the target file or dataset already exists.

--overwrite-layer

Whether overwriting the existing output vector layer is allowed.

--skip-errors

Added in version 3.12.

Whether failures to write feature(s) should be ignored. Note that this option sets the size of the transaction unit to one feature at a time, which may cause severe slowdown when inserting into databases.

--update

Whether to open an existing output dataset in update mode.

--upsert

Added in version 3.12.

Variant of `--append` where the *OGRLayer::UpsertFeature()* operation is used to insert or update features instead of appending with *OGRLayer::CreateFeature()*.

This is currently implemented only in a few drivers: *GPKG -- GeoPackage vector*, *Elasticsearch: Geographically Encoded Objects for Elasticsearch* and *MongoDBv3* (drivers that implement upsert expose the *GDAL_DCAP_UPSERT* capability).

The upsert operation uses the FID of the input feature, when it is set (and the FID column name is not the empty string), as the key to update existing features. It is crucial to make sure that the FID in the source and target layers are consistent.

For the GPKG driver, it is also possible to upsert features whose FID is unset or non-significant (the `--unset-fid` option of *gdal vector edit* can be used to ignore the FID from the source feature), when there is a UNIQUE column that is not the integer primary key.

Return status code

The program returns status code 0 in case of success, and non-zero in case of error (non-blocking errors emitted as warnings are considered as a successful execution).

Examples

Example 1: Output coverage errors in a TopoJSON file to a GeoJSON file

```
$ gdal vector check-coverage "https://cdn.jsdelivr.net/npm/us-atlas@3/counties-albers-
↪10m.json" --layer counties counties-errors.geojson
```

Example 2: Output invalid coverage features to the command-line as part of a pipeline

Bash

PowerShell

```
gdal vector pipeline \
    ! read "https://cdn.jsdelivr.net/npm/us-atlas@3/counties-albers-10m.json" --layer␣
↪counties \
    ! check-coverage \
    ! info --features
```

```
gdal vector pipeline `
    ! read "https://cdn.jsdelivr.net/npm/us-atlas@3/counties-albers-10m.json" --layer␣
↪counties `
    ! check-coverage `
    ! info --features
```

5.1.4.4 gdal vector check-geometry

Added in version 3.12.

Synopsis

```
Usage: gdal vector check-geometry [OPTIONS] <INPUT> <OUTPUT>

Check a dataset for invalid geometries

  --include-field <INCLUDE-FIELD>                       Fields from input layer to␣
↪include in output (special values: ALL and NONE) (default: NONE) [may be repeated]
  --include-valid                                       Include valid inputs in output,␣
↪with empty geometry
  --geometry-field <GEOMETRY-FIELD>                     Name of geometry field to check

Advanced Options:
  --if, --input-format <INPUT-FORMAT>                   Input formats [may be repeated]␣
↪[not available in pipelines]
  --oo, --open-option <KEY>=<VALUE>                     Open options [may be repeated]␣
↪[not available in pipelines]
  --output-oo, --output-open-option <KEY>=<VALUE>       Output open options [may be␣
↪repeated] [not available in pipelines]
  --upsert                                              Upsert features (implies 'append
↪') [not available in pipelines]
                                                        Mutually exclusive with --append
```

Description

gdal vector check-geometry checks that individual elements of a dataset are valid and simple according to the OGC Simple Features standard. For each invalid or non-simple feature, it will output a description and, in most cases, a point location of the error.

The following checks are performed, depending on the input geometry type:

- Polygons and MultiPolygons are checked for validity. A single point error point will be reported even if there are multiple causes of invalidity.
- LineStrings and MultiLineStrings are checked for simplicity. All self-intersection locations will be reported if GDAL is built using version 3.14 or later of the GEOS library. With earlier versions, self-intersection locations are not reported.
- GeometryCollections are checked that their individual elements are valid / simple. A single error point will be reported even if there are multiple causes of invalidity.
- Other geometry types are not checked.

Validity/simplicity checking is performed by the GEOS library and should be consistent with results of software such as PostGIS, QGIS, and shapely that also use that library. GEOS does not consider repeated points to be a cause of invalidity or non-simplicity. For more information about validity testing performed by **`gdal vector check-geometry`**, and examples of reported errors, see *Geometry Validity*.

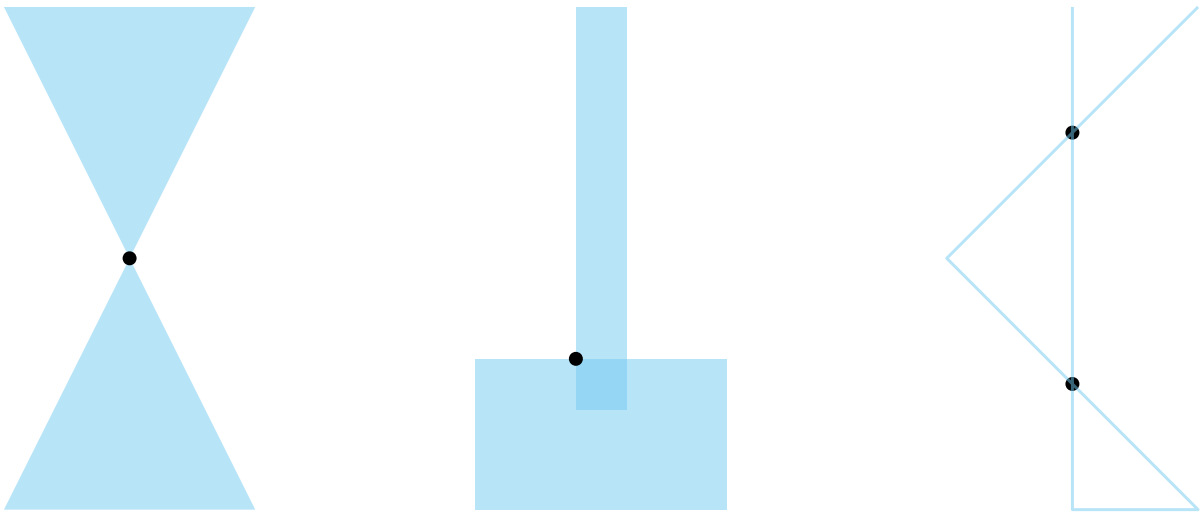

Fig. 11: Error locations reported by **`gdal vector check-geometry`** for Polygon, MultiPolyon, and LineString inputs.

Warning

Curved geometries are linearized before converting to GEOS. Linearized geometries may be valid/simple where the original geometries are not, and vice-versa.

GDALG output (on-the-fly / streamed dataset)

This program supports serializing the command line as a JSON file using the `GDALG` output format. The resulting file can then be opened as a vector dataset using the *GDALG: GDAL Streamed Algorithm* driver, and apply the specified pipeline in a on-the-fly / streamed way.

Note

However this algorithm is not natively streaming compatible. Consequently a in-memory temporary dataset will be generated, which may cause significant processing time at opening.

Program-Specific Options

--geometry-field

Specify the name of the geometry field to test, for layers having multiple geometry fields. By default the first geometry field will be used.

--include-field

Added in version 3.12.1.

Optional field(s) to copy from the input features to the output. Since GDAL 3.13, the value `ALL` can be used to include all fields from the source layer.

--include-valid

Include features for valid/simple geometries in the output, maintaining 1:1 correspondence between input and output features.

--input-layer `<INPUT-LAYER>`

Specifies the name of one or more layers to process. By default, all layers will be processed.

--output-layer

Specifies the name of the layer to which features will be written. If not specified and there is a single input layer, the name "error_location" will be used. If not specified and there are multiple input layers, features for each input layer will be written to a separate output layer in the format "error_location_{INPUT_LAYER}".

Standard Options

--append

Whether appending features to existing layer(s) is allowed. This also creates the output dataset if it does not exist yet.

--co, --creation-option `<NAME>=<VALUE>`

Many formats have one or more optional dataset creation options that can be used to control particulars about the file created. For instance, the GeoPackage driver supports creation options to control the version.

May be repeated.

The dataset creation options available vary by format driver, and some simple formats have no creation options at all. A list of options supported for a format can be listed with the *--formats* command line option but the documentation for the format is the definitive source of information on driver creation options. See *Vector drivers* format specific documentation for legal creation options for each format.

Note that dataset creation options are different from layer creation options.

--if, --input-format `<format>`

Format/driver name to be attempted to open the input file(s). It is generally not necessary to specify it, but it can be used to skip automatic driver detection, when it fails to select the appropriate driver. This option can be repeated several times to specify several candidate drivers. Note that it does not force those drivers to open the dataset. In particular, some drivers have requirements on file extensions.

May be repeated.

--lco, --layer-creation-option <NAME>=<VALUE>

Many formats have one or more optional layer creation options that can be used to control particulars about the layer created. For instance, the GeoPackage driver supports layer creation options to control the feature identifier or geometry column name, setting the identifier or description, etc.

May be repeated.

The layer creation options available vary by format driver, and some simple formats have no layer creation options at all. A list of options supported for a format can be listed with the *--formats* command line option but the documentation for the format is the definitive source of information on driver creation options. See *Vector drivers* format specific documentation for legal creation options for each format.

Note that layer creation options are different from dataset creation options.

--no-create-empty-layers

Added in version 3.13.

Avoid creating layers to which no features will be written.

--oo, --open-option <NAME>=<VALUE>

Dataset open option (format specific).

May be repeated.

-f, --of, --format, --output-format <OUTPUT-FORMAT>

Which output vector format to use. Allowed values may be given by `gdal --formats | grep vector | grep rw | sort`

--output-open-option, --output-oo <NAME>=<VALUE>

Added in version 3.12.

Dataset open option for output dataset (format specific).

May be repeated.

--overwrite

Allow program to overwrite existing target file or dataset. Otherwise, by default, **gdal** errors out if the target file or dataset already exists.

--overwrite-layer

Whether overwriting the existing output vector layer is allowed.

--skip-errors

Added in version 3.12.

Whether failures to write feature(s) should be ignored. Note that this option sets the size of the transaction unit to one feature at a time, which may cause severe slowdown when inserting into databases.

--update

Whether to open an existing output dataset in update mode.

--upsert

Added in version 3.12.

Variant of *--append* where the *OGRLayer::UpsertFeature()* operation is used to insert or update features instead of appending with *OGRLayer::CreateFeature()*.

This is currently implemented only in a few drivers: *GPKG -- GeoPackage vector*, *Elasticsearch: Geographically Encoded Objects for Elasticsearch* and *MongoDBv3* (drivers that implement upsert expose the *GDAL_DCAP_UPSERT* capability).

The upsert operation uses the FID of the input feature, when it is set (and the FID column name is not the empty string), as the key to update existing features. It is crucial to make sure that the FID in the source and target layers are consistent.

For the GPKG driver, it is also possible to upsert features whose FID is unset or non-significant (the `--unset-fid` option of *gdal vector edit* can be used to ignore the FID from the source feature), when there is a UNIQUE column that is not the integer primary key.

Return status code

The program returns status code 0 in case of success, and non-zero in case of error (non-blocking errors emitted as warnings are considered as a successful execution).

Examples

Example 1: Print invalidity locations to console

```
$ gdal vector check-geometry ne_10m_admin_0_countries.shp \
         --quiet \
         -f CSV \
         --lco GEOMETRY=AS_XY \
         --lco SEPARATOR=TAB \
         /vsistdout/
# X       Y       error
# 35.6210871060001       23.1392929140001        Ring Self-intersection
```

5.1.4.5 gdal vector clean-coverage

Added in version 3.12.

Synopsis

```
Usage: gdal vector clean-coverage [OPTIONS] <INPUT> <OUTPUT>

Alter polygon boundaries to make shared edges identical, removing gaps and overlaps

Positional arguments:
  -i, --input <INPUT>                                   Input vector datasets [required]␣
↪[not available in pipelines]
  -o, --output <OUTPUT>                                 Output vector dataset [required]␣
↪[not available in pipelines]

Common Options:
  -h, --help                                            Display help message and exit
  --json-usage                                          Display usage as JSON document␣
↪and exit
  --config <KEY>=<VALUE>                                Configuration option [may be␣
↪repeated]
  -q, --quiet                                           Quiet mode (no progress bar or␣
↪warning message) [not available in pipelines]

Options:
  -l, --layer, --input-layer <INPUT-LAYER>              Input layer name(s) [may be␣
```

↪repeated] [not available in pipelines]
  --upsert                                             Upsert features (implies 'append
↪') [not available in pipelines]
                                                       Mutually exclusive with --append
```

Description

gdal vector clean-coverage modifies boundaries of a polygonal dataset, such that gaps and overlaps between features are removed and shared edges are defined using the same vertices. The resulting dataset will form a polygonal coverage that can be used with *gdal vector simplify-coverage*.

This command can also be used as a step of *gdal vector pipeline*, although it requires loading the entire dataset into memory at once.

> **Note**
>
> This command requires a GDAL build against the GEOS library (version 3.14 or greater).

GDALG output (on-the-fly / streamed dataset)

This program supports serializing the command line as a JSON file using the `GDALG` output format. The resulting file can then be opened as a vector dataset using the *GDALG: GDAL Streamed Algorithm* driver, and apply the specified pipeline in a on-the-fly / streamed way.

> **Note**
>
> However this algorithm is not natively streaming compatible. Consequently a in-memory temporary dataset will be generated, which may cause significant processing time at opening.

Program-Specific Options

`--input-layer`

Specifies the name of the layer to process. By default, all layers will be processed.

`--maximum-gap-width` `<MAXIMUM-GAP-WIDTH>`

Defines the largest area that should be considered a "gap" and merged into an adjacent polygon. Gaps will be merged unless a circle with radius larger than the specified tolerance can be inscribed within the gap. The default maximum gap width is zero, meaning that gaps are not closed.

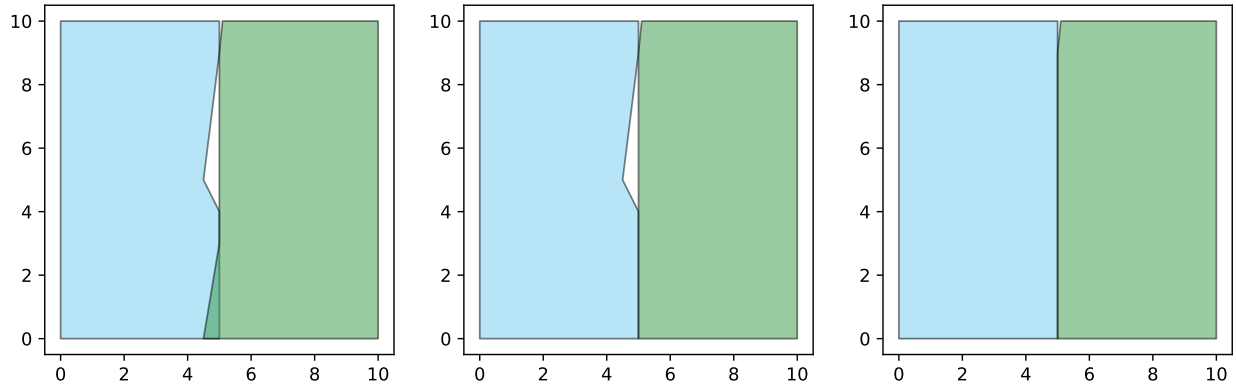

Fig. 12: Polygon dataset before cleaning (left), after cleaning with default parameters (center), and after cleaning with `--maximum-gap-width 1` (right).

`--merge-strategy` `<MERGE-STRATEGY>`

Method by which overlaps or gaps should be added to adjacent polygons. Options include: - longest-border (default): add areas to the polygon with which the longest border is shared - max-area: add areas to the largest adjacent polygon - min-area: add areas to the smallest adjacent polygon - min-index: add areas to the adjacent polygon that was read first

`--output-layer`

Specifies the name of the layer to which features will be written. By default, the names of the output layers will be the same as the names of the input layers.

`--snapping-distance` `<SNAPPING-DISTANCE>`

Controls the node snapping step, when nearby vertices are snapped together. By default, an automatic snapping distance is determined based on an analysis of the input. Set to zero to turn off all snapping.

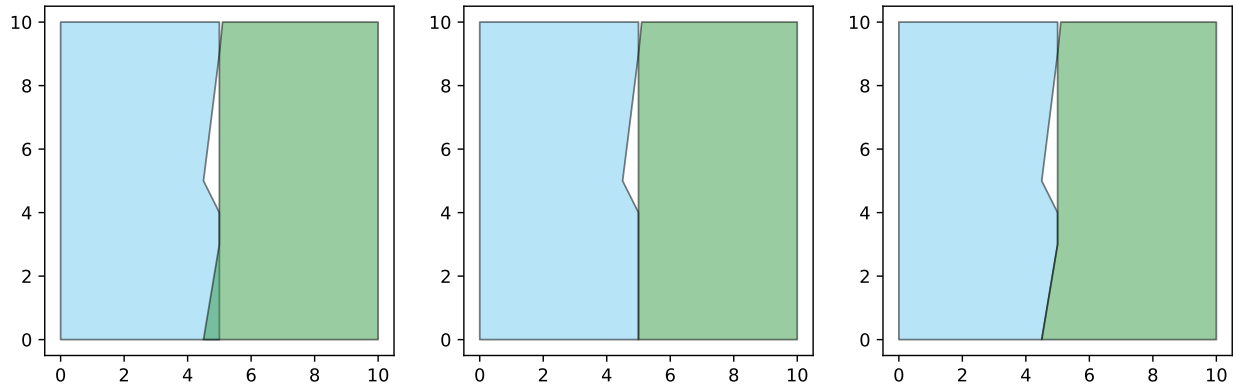

Fig. 13: Polygon dataset before cleaning (left), after cleaning with "longest-border" merge strategy (center) and `--merge-strategy max-area` (right).

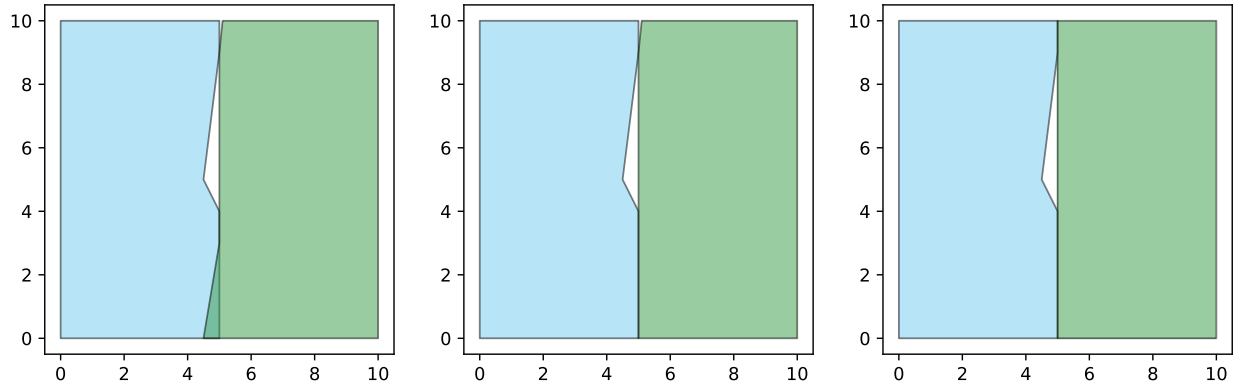

Fig. 14: Polygon dataset before cleaning (left), after cleaning with default snapping distance (center), and a more aggressive `--snapping-distance 0.2` (right). Note the movement in the upper-left corner of the polygon on the right.

Standard Options

--active-layer <ACTIVE-LAYER>

Set the active layer. When it is specified, only the layer specified by its name will be subject to the processing. Other layers will be not modified. If this option is not specified, all layers will be subject to the processing.

--append

Whether appending features to existing layer(s) is allowed. This also creates the output dataset if it does not exist yet.

--co, --creation-option <NAME>=<VALUE>

Many formats have one or more optional dataset creation options that can be used to control particulars about the file created. For instance, the GeoPackage driver supports creation options to control the version.

May be repeated.

The dataset creation options available vary by format driver, and some simple formats have no creation options at all. A list of options supported for a format can be listed with the *--formats* command line option but the documentation for the format is the definitive source of information on driver creation options. See *Vector drivers* format specific documentation for legal creation options for each format.

Note that dataset creation options are different from layer creation options.

--if, --input-format <format>

Format/driver name to be attempted to open the input file(s). It is generally not necessary to specify it, but it can be used to skip automatic driver detection, when it fails to select the appropriate driver. This option can be repeated several times to specify several candidate drivers. Note that it does not force those drivers to open the dataset. In particular, some drivers have requirements on file extensions.

May be repeated.

--lco, --layer-creation-option <NAME>=<VALUE>

Many formats have one or more optional layer creation options that can be used to control particulars about the layer created. For instance, the GeoPackage driver supports layer creation options to control the feature identifier or geometry column name, setting the identifier or description, etc.

May be repeated.

The layer creation options available vary by format driver, and some simple formats have no layer creation options at all. A list of options supported for a format can be listed with the *--formats* command line option but the documentation for the format is the definitive source of information on driver creation options. See *Vector drivers* format specific documentation for legal creation options for each format.

Note that layer creation options are different from dataset creation options.

--oo, --open-option <NAME>=<VALUE>

Dataset open option (format specific).

May be repeated.

-f, --of, --format, --output-format <OUTPUT-FORMAT>

Which output vector format to use. Allowed values may be given by `gdal --formats | grep vector | grep rw | sort`

--output-open-option, --output-oo <NAME>=<VALUE>

Added in version 3.12.

Dataset open option for output dataset (format specific).

May be repeated.

--overwrite

Allow program to overwrite existing target file or dataset. Otherwise, by default, **gdal** errors out if the target file or dataset already exists.

--overwrite-layer

Whether overwriting the existing output vector layer is allowed.

--skip-errors

Added in version 3.12.

Whether failures to write feature(s) should be ignored. Note that this option sets the size of the transaction unit to one feature at a time, which may cause severe slowdown when inserting into databases.

--update

Whether to open an existing output dataset in update mode.

--upsert

Added in version 3.12.

Variant of *--append* where the *OGRLayer::UpsertFeature()* operation is used to insert or update features instead of appending with *OGRLayer::CreateFeature()*.

This is currently implemented only in a few drivers: *GPKG -- GeoPackage vector*, *Elasticsearch: Geographically Encoded Objects for Elasticsearch* and *MongoDBv3* (drivers that implement upsert expose the *GDAL_DCAP_UPSERT* capability).

The upsert operation uses the FID of the input feature, when it is set (and the FID column name is not the empty string), as the key to update existing features. It is crucial to make sure that the FID in the source and target layers are consistent.

For the GPKG driver, it is also possible to upsert features whose FID is unset or non-significant (the `--unset-fid` option of *gdal vector edit* can be used to ignore the FID from the source feature), when there is a UNIQUE column that is not the integer primary key.

Return status code

The program returns status code 0 in case of success, and non-zero in case of error (non-blocking errors emitted as warnings are considered as a successful execution).

Examples

Example 1: Create and then simplify a polygonal coverage

```
$ gdal vector pipeline read ne_10m_admin_0_countries.shp ! \
                       make-valid ! \
                       clean-coverage ! \
                       simplify-coverage --tolerance 1 ! \
                       write countries.shp
```

5.1.4.6 gdal vector clip

Added in version 3.11.

Synopsis

```
Usage: gdal vector clip [OPTIONS] <INPUT> <OUTPUT>

Clip a vector dataset.

Positional arguments:
  -i, --input <INPUT>                                    Input vector datasets [required]␣

```

Description

gdal vector clip can be used to clip a vector dataset using georeferenced coordinates.

Either *--bbox*, *--geometry* or *--like* must be specified.

`clip` can also be used as a step of *gdal vector pipeline*.

Clipping sometimes results in geometries that are of a type not compatible with the geometry type. This program splits multi-geometries or geometry collections into their parts for layers that are of a single geometry type (such as point, linestring, polygon) and only keeps the parts that are of that type. It also promotes single geometry types (e.g. polygons) to multi geometry types (e.g. multi-polygons). If the user needs to preserve any type of intersection, the layer must use the `wkbUnknown` (any geometry) type.

Program-Specific Options

--bbox `<xmin>,<ymin>,<xmax>,<ymax>`

Bounds to which to clip the dataset. They are assumed to be in the CRS of the input dataset, unless *--bbox-crs* is specified. The X and Y axis are the "GIS friendly ones", that is X is longitude or easting, and Y is latitude or northing. Mutually exclusive with *--like* and *--geometry*.

--bbox-crs `<CRS>`

CRS in which the <xmin>,<ymin>,<xmax>,<ymax> values of *--bbox* are expressed. If not specified, it is assumed to be the CRS of the input dataset. Note that specifying --bbox-crs does not involve doing vector reprojection. Instead, the bounds are reprojected from the bbox-crs to the CRS of the input dataset.

--geometry `<WKT_or_GeoJSON>`

Geometry as a WKT or GeoJSON string to which to clip the dataset. If the input geometry is GeoJSON, its CRS is

assumed to be WGS84, unless there is a CRS defined in the GeoJSON geometry or *--geometry-crs* is specified. If the input geometry is WKT, its CRS is assumed to be the one of the input dataset, unless *--geometry-crs* is specified. The X and Y axis are the "GIS friendly ones", that is X is longitude or easting, and Y is latitude or northing. Mutually exclusive with *--bbox* and *--like*.

--geometry-crs <CRS>

CRS in which the coordinates values of *--geometry* are expressed. If not specified, it is assumed to be the CRS of the input dataset. Note that specifying --geometry-crs does not involve doing vector reprojection. Instead, the bounds are reprojected from the geometry-crs to the CRS of the input dataset.

--like <DATASET>

Vector or raster dataset to use as a template for bounds. If the specified dataset is a raster, its rectangular bounds are used as the clipping geometry. If the specified dataset is a vector dataset, its polygonal geometries are unioned together to form the clipping geometry (beware that the result union might not be perfect if there are gaps between individual polygon features). If several layers are present, *--like-sql* or *--like-layer* must be specified. Mutually exclusive with *--bbox* and *--geometry*.

--like-layer <LAYER-NAME>

Select the named layer from the vector clip dataset. Mutually exclusive with *--like-sql*

--like-sql <SELECT-STATEMENT>

Select desired geometries from the vector clip dataset using an SQL query. e.g `SELECT geom FROM my_layer WHERE country = 'France'`. Mutually exclusive with *--like-layer* and *--like-where*

--like-where <WHERE-EXPRESSION>

Restrict desired geometries from vector clip dataset layer based on an attribute query. e.g `country = 'France'`.

Standard Options

--active-layer <ACTIVE-LAYER>

Set the active layer. When it is specified, only the layer specified by its name will be subject to the processing. Other layers will be not modified. If this option is not specified, all layers will be subject to the processing.

--append

Whether appending features to existing layer(s) is allowed. This also creates the output dataset if it does not exist yet.

--co, --creation-option <NAME>=<VALUE>

Many formats have one or more optional dataset creation options that can be used to control particulars about the file created. For instance, the GeoPackage driver supports creation options to control the version.

May be repeated.

The dataset creation options available vary by format driver, and some simple formats have no creation options at all. A list of options supported for a format can be listed with the *--formats* command line option but the documentation for the format is the definitive source of information on driver creation options. See *Vector drivers* format specific documentation for legal creation options for each format.

Note that dataset creation options are different from layer creation options.

--if, --input-format <format>

Format/driver name to be attempted to open the input file(s). It is generally not necessary to specify it, but it can be used to skip automatic driver detection, when it fails to select the appropriate driver. This option can be repeated several times to specify several candidate drivers. Note that it does not force those drivers to open the dataset. In particular, some drivers have requirements on file extensions.

May be repeated.

--input-layer <INPUT-LAYER>

Specifies the name of one or more layers to process. By default, all layers will be processed. To read and write all layers but only process a subset, use *--active-layer*.

--lco, --layer-creation-option <NAME>=<VALUE>

Many formats have one or more optional layer creation options that can be used to control particulars about the layer created. For instance, the GeoPackage driver supports layer creation options to control the feature identifier or geometry column name, setting the identifier or description, etc.

May be repeated.

The layer creation options available vary by format driver, and some simple formats have no layer creation options at all. A list of options supported for a format can be listed with the *--formats* command line option but the documentation for the format is the definitive source of information on driver creation options. See *Vector drivers* format specific documentation for legal creation options for each format.

Note that layer creation options are different from dataset creation options.

--oo, --open-option <NAME>=<VALUE>

Dataset open option (format specific).

May be repeated.

-f, --of, --format, --output-format <OUTPUT-FORMAT>

Which output vector format to use. Allowed values may be given by `gdal --formats | grep vector | grep rw | sort`

--output-layer <NAME>

Specifies the name of the layer to which features will be written. If not specified, output layer names will be the same as input layer names.

--output-open-option, --output-oo <NAME>=<VALUE>

Added in version 3.12.

Dataset open option for output dataset (format specific).

May be repeated.

--overwrite

Allow program to overwrite existing target file or dataset. Otherwise, by default, **gdal** errors out if the target file or dataset already exists.

--overwrite-layer

Whether overwriting the existing output vector layer is allowed.

--skip-errors

Added in version 3.12.

Whether failures to write feature(s) should be ignored. Note that this option sets the size of the transaction unit to one feature at a time, which may cause severe slowdown when inserting into databases.

--update

Whether to open an existing output dataset in update mode.

--upsert

Added in version 3.12.

Variant of *--append* where the *OGRLayer::UpsertFeature()* operation is used to insert or update features instead of appending with *OGRLayer::CreateFeature()*.

This is currently implemented only in a few drivers: *GPKG -- GeoPackage vector*, *Elasticsearch: Geographically Encoded Objects for Elasticsearch* and *MongoDBv3* (drivers that implement upsert expose the *GDAL_DCAP_UPSERT* capability).

The upsert operation uses the FID of the input feature, when it is set (and the FID column name is not the empty string), as the key to update existing features. It is crucial to make sure that the FID in the source and target layers are consistent.

For the GPKG driver, it is also possible to upsert features whose FID is unset or non-significant (the `--unset-fid` option of *gdal vector edit* can be used to ignore the FID from the source feature), when there is a UNIQUE column that is not the integer primary key.

Return status code

The program returns status code 0 in case of success, and non-zero in case of error (non-blocking errors emitted as warnings are considered as a successful execution).

Examples

Example 1: Clip a GeoPackage file to the bounding box from longitude 2, latitude 49, to longitude 3, latitude 50 in WGS 84

```
$ gdal vector clip --bbox=2,49,3,50 --bbox-crs=EPSG:4326 in.gpkg out.gpkg --overwrite
```

5.1.4.7 gdal vector combine

Added in version 3.13.

Synopsis

```
Usage: gdal vector combine [OPTIONS] <INPUT> <OUTPUT>

Combine features into collections

Positional arguments:
  -i, --input <INPUT>                                    Input vector datasets [required]␣
↪[not available in pipelines]
  -o, --output <OUTPUT>                                  Output vector dataset [required]␣
↪[not available in pipelines]

Common Options:
  -h, --help                                             Display help message and exit
  --json-usage                                           Display usage as JSON document␣
↪and exit
  --config <KEY>=<VALUE>                                 Configuration option [may be␣
↪repeated]
  -q, --quiet                                            Quiet mode (no progress bar or␣
↪warning message) [not available in pipelines]

Options:
  -l, --layer, --input-layer <INPUT-LAYER>               Input layer name(s) [may be␣
↪repeated] [not available in pipelines]
  -f, --of, --format, --output-format <OUTPUT-FORMAT>  Output format ("GDALG" allowed)␣
↪[not available in pipelines]
```

↪') [not available in pipelines]
                                                       Mutually exclusive with --append
```

Description

gdal vector combine combines geometries into geometry collections.

The *--group-by* argument can be used to determine which features are combined.

By default, the parts of multipart geometries will be combined into an un-nested collection of the most specific type possible (e.g., `MultiPolygon` rather than `GeometryCollection`). For example, a Polygon and a two-part MultiPolygon would be combined into a three-part MultiPoygon. This is done because many GIS file formats and software packages do not handle nested GeometryCollections types. If the nested representation in the manner of PostGIS' `ST_Collect` is preferred (a two-component GeometryCollection containing the Polygon and MultiPolygon), then *--keep-nested* can be used.

`combine` can be used as a step of *gdal vector pipeline*.

Program-Specific Options

--group-by <FIELD_NAMES>

The names of fields whose unique values will be used to collect input geometries. Any fields not listed in *--group-by* will be removed from the source layer. If *--group-by* is omitted, the entire layer will be combined into a single feature.

--keep-nested

If input geometries have multiple parts, combine them into a GeometryCollection of the input geometries.

--add-extra-fields no|sometimes-identical|always-identical

Whether fields from source features that have the same value among the features belonging to a same group are copied to the corresponding output feature.

By default, no, only fields listed in *--group-by* are copied to the output layer.

When specifying sometimes-identical, fields, for which all input features within at least one output group have the same value, will be copied to the output layer schema. The value of the field is the value that is common for all input features of a group. If the input features within some group are not identical, the field value in the output for this group will be set to null.

When specifying always-identical, fields for which all input features within a given output group have the same value are copied to the output layer, provided this condition holds for all output groups.

For example, let's suppose we have four input features with the following content, and we group them by country

Table 2: Input features

name	country	country_fr	type
Mainland France	France	France	continental
Corsica	France	France	island
Mainland USA	USA	Etats-Unis d'Amérique	continental
Alaska	USA	Etats-Unis d'Amérique	continental

With sometimes-identical, the output will be:

Table 3: Output with sometimes-identical

country	country_fr	type
France	France	
USA	Etats-Unis d'Amérique	continental

The name field has been removed because it is distinct for each input feature. The type field appears as an output field, because at least for the USA, the two grouped input features that makes it have the same value. For France, its content is set to null, because its value is different in the two input features.

With always-identical, the output will be:

Table 4: Output with always-identical

country	country_fr
France	France
USA	Etats-Unis d'Amérique

The type field has been removed because its value is different in the two input features of France.

Return status code

The program returns status code 0 in case of success, and non-zero in case of error (non-blocking errors emitted as warnings are considered as a successful execution).

Standard Options

--append

Whether appending features to existing layer(s) is allowed. This also creates the output dataset if it does not exist yet.

--co, --creation-option <NAME>=<VALUE>

Many formats have one or more optional dataset creation options that can be used to control particulars about the file created. For instance, the GeoPackage driver supports creation options to control the version.

May be repeated.

The dataset creation options available vary by format driver, and some simple formats have no creation options at all. A list of options supported for a format can be listed with the *--formats* command line option but the documentation for the format is the definitive source of information on driver creation options. See *Vector drivers* format specific documentation for legal creation options for each format.

Note that dataset creation options are different from layer creation options.

--if, --input-format <format>

Format/driver name to be attempted to open the input file(s). It is generally not necessary to specify it, but it can be used to skip automatic driver detection, when it fails to select the appropriate driver. This option can be repeated several times to specify several candidate drivers. Note that it does not force those drivers to open the dataset. In particular, some drivers have requirements on file extensions.

May be repeated.

--lco, --layer-creation-option <NAME>=<VALUE>

Many formats have one or more optional layer creation options that can be used to control particulars about the layer created. For instance, the GeoPackage driver supports layer creation options to control the feature identifier or geometry column name, setting the identifier or description, etc.

May be repeated.

The layer creation options available vary by format driver, and some simple formats have no layer creation options at all. A list of options supported for a format can be listed with the *--formats* command line option but the documentation for the format is the definitive source of information on driver creation options. See *Vector drivers* format specific documentation for legal creation options for each format.

Note that layer creation options are different from dataset creation options.

--oo, --open-option <NAME>=<VALUE>

Dataset open option (format specific).

May be repeated.

-f, --of, --format, --output-format <OUTPUT-FORMAT>

Which output vector format to use. Allowed values may be given by `gdal --formats | grep vector | grep rw | sort`

--output-open-option, --output-oo <NAME>=<VALUE>

Added in version 3.12.

Dataset open option for output dataset (format specific).

May be repeated.

--overwrite

Allow program to overwrite existing target file or dataset. Otherwise, by default, **gdal** errors out if the target file or dataset already exists.

--overwrite-layer

Whether overwriting the existing output vector layer is allowed.

--skip-errors

Added in version 3.12.

Whether failures to write feature(s) should be ignored. Note that this option sets the size of the transaction unit to one feature at a time, which may cause severe slowdown when inserting into databases.

--update

Whether to open an existing output dataset in update mode.

--upsert

Added in version 3.12.

Variant of *--append* where the *OGRLayer::UpsertFeature()* operation is used to insert or update features instead of appending with *OGRLayer::CreateFeature()*.

This is currently implemented only in a few drivers: *GPKG -- GeoPackage vector*, *Elasticsearch: Geographically Encoded Objects for Elasticsearch* and *MongoDBv3* (drivers that implement upsert expose the *GDAL_DCAP_UPSERT* capability).

The upsert operation uses the FID of the input feature, when it is set (and the FID column name is not the empty string), as the key to update existing features. It is crucial to make sure that the FID in the source and target layers are consistent.

For the GPKG driver, it is also possible to upsert features whose FID is unset or non-significant (the `--unset-fid` option of *gdal vector edit* can be used to ignore the FID from the source feature), when there is a UNIQUE column that is not the integer primary key.

5.1.4.8 gdal vector concat

Added in version 3.11.

Synopsis

```
Usage: gdal vector concat [OPTIONS] <INPUTS>... <OUTPUT>

Concatenate vector datasets.

Positional arguments:
  -i, --input <INPUTS>                                      Input vector datasets [1..␣

↪'append') [not available in pipelines]
                                                                Mutually exclusive with --
↪append
```

Description

gdal vector concat concatenates several source datasets.

It has 3 main modes:

- *--mode* = `merge-per-layer-name` (the default). The output dataset generated by the command will contain as many layers as there are different layer names in the source datasets. For example if there are 2 datasets, one with layers *a* and *b*, and the other one with layers *b* and *c*, 3 output layers will be created: *a*, *b* (merging the 2 source layers) and *c*.
- *--mode* = `stack`. The output dataset generated by the command will contain as many layers as there are layers in the source datasets. For example if there are 2 datasets `ds1` (with layers *a* and *b*) and `ds2` (with layers *b* and *c*), 4 output layers will be created: `ds1_a`, `ds1_b`, `ds2_b` and `ds2_c`.
- *--mode* = `single`. The output dataset generated by the command will contain one single layer, merging all layers in the source datasets.

When an output layer merges several source layer, by default the resulting schema will contain the union of all source fields. It is possible to select only the intersection with the *--field-strategy* set to `intersection`. Regarding the resulting CRS, by default the CRS of the source layer will be used as the target CRS, and features of other source layers that do no match this CRS will be reprojected to it. *--output-crs* can be used to select a given destination CRS.

This command can also be used as the first step of *gdal vector pipeline*.

GDALG output (on-the-fly / streamed dataset)

This program supports serializing the command line as a JSON file using the `GDALG` output format. The resulting file can then be opened as a vector dataset using the *GDALG: GDAL Streamed Algorithm* driver, and apply the specified pipeline in a on-the-fly / streamed way.

Program-Specific Options

--field-strategy `union|intersection`

Determines how the schema of the target layer is built from the schemas of the input layers:

- `union` (default) to use a super-set of all the fields from all source layers.
- `intersection` to use a sub-set of all the common fields from all source layers.

--input-crs, -s `<INPUT-CRS>`

Set (override) input spatial reference. If not specified the SRS found in the input dataset will be used.

The coordinate reference systems that can be passed are anything supported by the OGRSpatialReference.SetFromUserInput() call, which includes EPSG Projected, Geographic or Compound CRS (i.e. EPSG:4296), a well known text (WKT) CRS definition, PROJ.4 declarations, or the name of a .prj file containing a WKT CRS definition.

If the SRS has an explicit vertical datum that points to a geoid grid, and the input dataset is a single band dataset, a vertical correction will be applied to the values of the dataset.

--mode `merge-per-layer-name|stack|single`

Determine the strategy to create output layers from source layers. See introductory paragraph for more details.

--output-crs, -d `<OUTPUT-CRS>`

Set output spatial reference. Inputs will be reprojected to this CRS if necessary.

The coordinate reference systems that can be passed are anything supported by the OGRSpatialReference.SetFromUserInput() call, which includes EPSG Projected, Geographic or Compound CRS (i.e.

EPSG:4296), a well known text (WKT) CRS definition, PROJ.4 declarations, or the name of a .prj file containing a WKT CRS definition.

If the SRS has an explicit vertical datum that points to a geoid grid, and the input dataset is a single band dataset, a vertical correction will be applied to the values of the dataset.

--output-layer <OUTPUT-LAYER>

Name of the output vector layer (in `single` mode, and the default is "merged"), or template to name the output vector layers in `stack` mode (the default value is `{AUTO_NAME}`). Not allowed in `merge-per-layer-name` mode.

The template in `stack` mode can be a string with the following variables that will be substituted with a value computed from the input layer being processed:

- `{AUTO_NAME}`: equivalent to `{DS_BASENAME}_{LAYER_NAME}` if both values are different, or `{LAYER_NAME}` when they are identical (case of shapefile).
- `{DS_NAME}`: name of the source dataset
- `{DS_BASENAME}`: base name of the source dataset
- `{DS_INDEX}`: index of the source dataset
- `{LAYER_NAME}`: name of the source layer
- `{LAYER_INDEX}`: index of the source layer

--source-layer-field-content <SOURCE-LAYER-FIELD-CONTENT>

If specified, the schema of the target layer will be extended with a new field (whose name is given by *--source-layer-field-name*, or `source_ds_lyr` otherwise), whose content is determined by the specified template (see *--output-layer* for variables that can be used).

--source-layer-field-name <SOURCE-LAYER-FIELD-NAME>

If specified, the schema of the target layer will be extended with a field whose name is the value of this option and whose content is determined *--source-layer-field-content*.

Standard Options

--append

Whether appending features to existing layer(s) is allowed. This also creates the output dataset if it does not exist yet.

--co, --creation-option <NAME>=<VALUE>

Many formats have one or more optional dataset creation options that can be used to control particulars about the file created. For instance, the GeoPackage driver supports creation options to control the version.

May be repeated.

The dataset creation options available vary by format driver, and some simple formats have no creation options at all. A list of options supported for a format can be listed with the *--formats* command line option but the documentation for the format is the definitive source of information on driver creation options. See *Vector drivers* format specific documentation for legal creation options for each format.

Note that dataset creation options are different from layer creation options.

--if, --input-format <format>

Format/driver name to be attempted to open the input file(s). It is generally not necessary to specify it, but it can be used to skip automatic driver detection, when it fails to select the appropriate driver. This option can be repeated several times to specify several candidate drivers. Note that it does not force those drivers to open the dataset. In particular, some drivers have requirements on file extensions.

May be repeated.

--input-layer <INPUT-LAYER>

Specifies the name of one or more layers to process. By default, all layers will be processed.

--lco, --layer-creation-option <NAME>=<VALUE>

Many formats have one or more optional layer creation options that can be used to control particulars about the layer created. For instance, the GeoPackage driver supports layer creation options to control the feature identifier or geometry column name, setting the identifier or description, etc.

May be repeated.

The layer creation options available vary by format driver, and some simple formats have no layer creation options at all. A list of options supported for a format can be listed with the *--formats* command line option but the documentation for the format is the definitive source of information on driver creation options. See *Vector drivers* format specific documentation for legal creation options for each format.

Note that layer creation options are different from dataset creation options.

--oo, --open-option <NAME>=<VALUE>

Dataset open option (format specific).

May be repeated.

-f, --of, --format, --output-format <OUTPUT-FORMAT>

Which output vector format to use. Allowed values may be given by `gdal --formats | grep vector | grep rw | sort`

--output-open-option, --output-oo <NAME>=<VALUE>

Added in version 3.12.

Dataset open option for output dataset (format specific).

May be repeated.

--overwrite

Allow program to overwrite existing target file or dataset. Otherwise, by default, **gdal** errors out if the target file or dataset already exists.

--overwrite-layer

Whether overwriting the existing output vector layer is allowed.

--skip-errors

Added in version 3.12.

Whether failures to write feature(s) should be ignored. Note that this option sets the size of the transaction unit to one feature at a time, which may cause severe slowdown when inserting into databases.

--update

Whether to open an existing output dataset in update mode.

--upsert

Added in version 3.12.

Variant of *--append* where the *OGRLayer::UpsertFeature()* operation is used to insert or update features instead of appending with *OGRLayer::CreateFeature()*.

This is currently implemented only in a few drivers: *GPKG -- GeoPackage vector*, *Elasticsearch: Geographically Encoded Objects for Elasticsearch* and *MongoDBv3* (drivers that implement upsert expose the *GDAL_DCAP_UPSERT* capability).

The upsert operation uses the FID of the input feature, when it is set (and the FID column name is not the empty string), as the key to update existing features. It is crucial to make sure that the FID in the source and target layers are consistent.

For the GPKG driver, it is also possible to upsert features whose FID is unset or non-significant (the `--unset-fid` option of *gdal vector edit* can be used to ignore the FID from the source feature), when there is a UNIQUE column that is not the integer primary key.

Return status code

The program returns status code 0 in case of success, and non-zero in case of error (non-blocking errors emitted as warnings are considered as a successful execution).

Examples

Example 1: Creating a GeoPackage stacking all input shapefiles in separate layers.

```
gdal vector concat --mode=stack *.shp out.gpkg
```

Example 2: Adding a field to indicate the source layer, and reprojecting to a single CRS

Concatenate the content of `france.shp` and `germany.shp` in `merged.shp`, reprojecting them to ETRS89, and add a 'country' field to each feature whose value is 'france' or 'germany' depending where it comes from:

```
gdal vector concat --mode=single --source-layer-field-name=country --output-
↪crs=EPSG:4258 france.shp germany.shp merged.shp
```

5.1.4.9 gdal vector concave-hull

Added in version 3.13.

Synopsis

```
Usage: gdal vector concave-hull [OPTIONS] <INPUT> <OUTPUT>

Compute the concave hull of geometries of a vector dataset.

Positional arguments:
  -i, --input <INPUT>                                    Input vector datasets [required]␣
↪[not available in pipelines]
  -o, --output <OUTPUT>                                  Output vector dataset [required]␣
↪[not available in pipelines]

Common Options:
  -h, --help                                             Display help message and exit
  --json-usage                                           Display usage as JSON document␣
↪and exit
  --config <KEY>=<VALUE>                                 Configuration option [may be␣
↪repeated]
  -q, --quiet                                            Quiet mode (no progress bar or␣
↪warning message) [not available in pipelines]

Options:
```

(continues on next page)

(continued from previous page)

```
  -l, --layer, --input-layer <INPUT-LAYER>             Input layer name(s) [may be␣
↪repeated] [not available in pipelines]
  -f, --of, --format, --output-format <OUTPUT-FORMAT>  Output format ("GDALG" allowed)␣
↪[not available in pipelines]

↪output layer is allowed [not available in pipelines]
  --append                                             Whether appending to existing␣
↪layer is allowed [not available in pipelines]
                                                       Mutually exclusive with --upsert
  --output-layer <OUTPUT-LAYER>                        Output layer name [not available␣
↪in pipelines]
  --skip-errors                                        Skip errors when writing features␣
↪[not available in pipelines]
  --active-layer <ACTIVE-LAYER>                        Set active layer (if not␣
↪specified, all)
  --active-geometry <ACTIVE-GEOMETRY>                  Geometry field name to which to␣
↪restrict the processing (if not specified, all)
  --ratio <RATIO>                                      Ratio controlling the concavity␣
↪[required]
  --allow-holes                                        Allow holes in the output polygon
  --tight                                              Whether the hull must follow the␣
↪outer boundaries of the input polygons

Advanced Options:
  --if, --input-format <INPUT-FORMAT>                  Input formats [may be repeated]␣
↪[not available in pipelines]
  --oo, --open-option <KEY>=<VALUE>                    Open options [may be repeated]␣
↪[not available in pipelines]
  --output-oo, --output-open-option <KEY>=<VALUE>      Output open options [may be␣
↪repeated] [not available in pipelines]
  --upsert                                             Upsert features (implies 'append
↪') [not available in pipelines]
                                                       Mutually exclusive with --append
```

Description

gdal vector concave-hull computes the smallest concave polygon that covers the input geometry. Generally the result will be a Polygon, but for degenerate inputs it may be a LineString or a Point. It uses the *OGRGeometry::ConcaveHullOfPolygons()* method for polygonal input, and *OGRGeometry::ConcaveHull()* otherwise.

This command can also be used as a step of *gdal vector pipeline*.

GDALG output (on-the-fly / streamed dataset)

This program supports serializing the command line as a JSON file using the `GDALG` output format. The resulting file can then be opened as a vector dataset using the *GDALG: GDAL Streamed Algorithm* driver, and apply the specified pipeline in a on-the-fly / streamed way.

> **Note**
>
> This command requires a GDAL build against the GEOS library.

Program-Specific Options

--allow-holes

Allow result polygons to contain holes.

--tight

Whether the hull must follow the outer boundaries of the input polygons.

--ratio <RATIO>

Ratio controlling the concavity of the geometry.

A value of 1 produces the convex hull; decreasing values of the ratio generally produce polygons of increasing concavity (and with polygonal input, a value of 0 produces the original polygons).

Standard Options

--append

Whether appending features to existing layer(s) is allowed. This also creates the output dataset if it does not exist yet.

--active-layer <ACTIVE-LAYER>

Set the active layer. When it is specified, only the layer specified by its name will be subject to the processing. Other layers will be not modified. If this option is not specified, all layers will be subject to the processing.

--active-geometry <ACTIVE-GEOMETRY>

Set the active geometry field from its name. When it is specified, only the specified geometry field will be subject to the processing. Other geometry fields will be not modified. If this option is not specified, all geometry fields will be subject to the processing. This option can be combined together with `--active-layer`.

--co, --creation-option <NAME>=<VALUE>

Many formats have one or more optional dataset creation options that can be used to control particulars about the file created. For instance, the GeoPackage driver supports creation options to control the version.

May be repeated.

The dataset creation options available vary by format driver, and some simple formats have no creation options at all. A list of options supported for a format can be listed with the *--formats* command line option but the documentation for the format is the definitive source of information on driver creation options. See *Vector drivers* format specific documentation for legal creation options for each format.

Note that dataset creation options are different from layer creation options.

--if, --input-format <format>

Format/driver name to be attempted to open the input file(s). It is generally not necessary to specify it, but it can be used to skip automatic driver detection, when it fails to select the appropriate driver. This option can be

repeated several times to specify several candidate drivers. Note that it does not force those drivers to open the dataset. In particular, some drivers have requirements on file extensions.

May be repeated.

--input-layer <INPUT-LAYER>

Specifies the name of one or more layers to process. By default, all layers will be processed. To read and write all layers but only process a subset, use *--active-layer*.

--lco, --layer-creation-option <NAME>=<VALUE>

Many formats have one or more optional layer creation options that can be used to control particulars about the layer created. For instance, the GeoPackage driver supports layer creation options to control the feature identifier or geometry column name, setting the identifier or description, etc.

May be repeated.

The layer creation options available vary by format driver, and some simple formats have no layer creation options at all. A list of options supported for a format can be listed with the *--formats* command line option but the documentation for the format is the definitive source of information on driver creation options. See *Vector drivers* format specific documentation for legal creation options for each format.

Note that layer creation options are different from dataset creation options.

--oo, --open-option <NAME>=<VALUE>

Dataset open option (format specific).

May be repeated.

-f, --of, --format, --output-format <OUTPUT-FORMAT>

Which output vector format to use. Allowed values may be given by `gdal --formats | grep vector | grep rw | sort`

--output-layer <NAME>

Specifies the name of the layer to which features will be written. If not specified, output layer names will be the same as input layer names.

--output-open-option, --output-oo <NAME>=<VALUE>

Added in version 3.12.

Dataset open option for output dataset (format specific).

May be repeated.

--overwrite

Allow program to overwrite existing target file or dataset. Otherwise, by default, **gdal** errors out if the target file or dataset already exists.

--overwrite-layer

Whether overwriting the existing output vector layer is allowed.

--skip-errors

Added in version 3.12.

Whether failures to write feature(s) should be ignored. Note that this option sets the size of the transaction unit to one feature at a time, which may cause severe slowdown when inserting into databases.

--update

Whether to open an existing output dataset in update mode.

--upsert

Added in version 3.12.

Variant of *--append* where the *OGRLayer::UpsertFeature()* operation is used to insert or update features instead of appending with *OGRLayer::CreateFeature()*.

This is currently implemented only in a few drivers: *GPKG -- GeoPackage vector*, *Elasticsearch: Geographically Encoded Objects for Elasticsearch* and *MongoDBv3* (drivers that implement upsert expose the *GDAL_DCAP_UPSERT* capability).

The upsert operation uses the FID of the input feature, when it is set (and the FID column name is not the empty string), as the key to update existing features. It is crucial to make sure that the FID in the source and target layers are consistent.

For the GPKG driver, it is also possible to upsert features whose FID is unset or non-significant (the `--unset-fid` option of *gdal vector edit* can be used to ignore the FID from the source feature), when there is a UNIQUE column that is not the integer primary key.

Examples

Example 1: Compute the concave hull of city locations in each country

Here the Natural Earth Populated Places dataset is used. To ensure that a polygonal hull is generated for each country, the input points are first buffered by a small amount. Otherwise, countries having only one or two cities would end up with a point or line geometry.

```
gdal vector pipeline ! \
    read ne_10m_populated_places.shp ! \
    buffer 0.1 ! \
    combine --group-by ADM0_A3 ! \
    concave-hull --ratio 0.5 ! \
    write country_city_hulls.gpkg
```

Example 2: Compute the concave hull of polygons of all countries, starting with their internal administrative divisions.

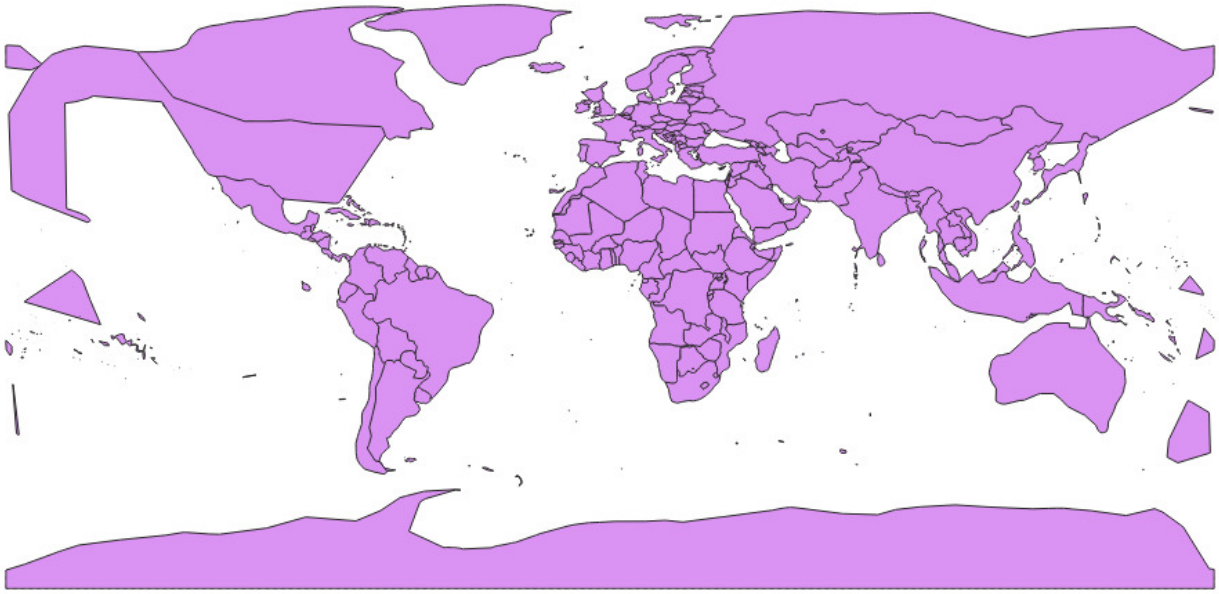
We use the "Admin 1 - States, Provinces" dataset, so that islands and oversea territories are in distinct polygonal features, to get a better looking result than if we started from "Admin 0 - Countries", where for example Bouvet Island in the South Atlantic is in the same multipolygon feature as mainland Norway.

The *combine* stage helps merging together administrative divisions of a same country with geographic proximity.

The *dissolve* stage transforms each geometry collection resulting from the previous stage into a valid polygon/multipolygon, as required by the concave hull by polygons algorithm.

The `sql` stage helps rendering smaller countries on top of larger ones.

```
gdal vector pipeline ! \
    read /vsizip//vsicurl/https://naciscdn.org/naturalearth/10m/cultural/ne_10m_admin_1_
↪states_provinces.zip ! \
    combine --group-by admin,geonunit ! \
    dissolve ! \
    concave-hull --ratio 0.1 ! \
    rename-layer --output-layer countries_concave_hull_of_polygons ! \
    sql --sql "SELECT * FROM countries_concave_hull_of_polygons ORDER BY ST_
↪Area(geometry) DESC" --dialect SQLite ! \
    write countries_concave_hull_of_polygons.gpkg
```



5.1.4.10 gdal vector convert

Added in version 3.11.

Synopsis

```
Usage: gdal vector convert [OPTIONS] <INPUT> <OUTPUT>

Convert a vector dataset.

Positional arguments:
  -i, --input <INPUT>                                    Input vector datasets [required]␣
↪[not available in pipelines]
  -o, --output <OUTPUT>                                  Output vector dataset [required]␣

↪repeated] [not available in pipelines]
  --upsert                                             Upsert features (implies 'append
↪') [not available in pipelines]
                                                       Mutually exclusive with --append
```

Description

gdal vector convert can be used to convert data data between different formats.

Standard Options

--append

Whether appending features to existing layer(s) is allowed. This also creates the output dataset if it does not exist yet.

--co, --creation-option <NAME>=<VALUE>

Many formats have one or more optional dataset creation options that can be used to control particulars about the file created. For instance, the GeoPackage driver supports creation options to control the version.

May be repeated.

The dataset creation options available vary by format driver, and some simple formats have no creation options at all. A list of options supported for a format can be listed with the *--formats* command line option but the documentation for the format is the definitive source of information on driver creation options. See *Vector drivers* format specific documentation for legal creation options for each format.

Note that dataset creation options are different from layer creation options.

--if, --input-format <format>

Format/driver name to be attempted to open the input file(s). It is generally not necessary to specify it, but it

can be used to skip automatic driver detection, when it fails to select the appropriate driver. This option can be repeated several times to specify several candidate drivers. Note that it does not force those drivers to open the dataset. In particular, some drivers have requirements on file extensions.

May be repeated.

--input-layer <INPUT-LAYER>

Specifies the name of one or more layers to process. By default, all layers will be processed.

--lco, --layer-creation-option <NAME>=<VALUE>

Many formats have one or more optional layer creation options that can be used to control particulars about the layer created. For instance, the GeoPackage driver supports layer creation options to control the feature identifier or geometry column name, setting the identifier or description, etc.

May be repeated.

The layer creation options available vary by format driver, and some simple formats have no layer creation options at all. A list of options supported for a format can be listed with the *--formats* command line option but the documentation for the format is the definitive source of information on driver creation options. See *Vector drivers* format specific documentation for legal creation options for each format.

Note that layer creation options are different from dataset creation options.

--no-create-empty-layers

Added in version 3.13.

Avoid creating layers to which no features will be written.

--oo, --open-option <NAME>=<VALUE>

Dataset open option (format specific).

May be repeated.

-f, --of, --format, --output-format <OUTPUT-FORMAT>

Which output vector format to use. Allowed values may be given by `gdal --formats | grep vector | grep rw | sort`

--output-layer <NAME>

Specifies the name of the layer to which features will be written. If not specified, output layer names will be the same as input layer names.

--output-open-option, --output-oo <NAME>=<VALUE>

Added in version 3.12.

Dataset open option for output dataset (format specific).

May be repeated.

--overwrite

Allow program to overwrite existing target file or dataset. Otherwise, by default, **gdal** errors out if the target file or dataset already exists.

--overwrite-layer

Whether overwriting the existing output vector layer is allowed.

--skip-errors

Added in version 3.12.

Whether failures to write feature(s) should be ignored. Note that this option sets the size of the transaction unit to one feature at a time, which may cause severe slowdown when inserting into databases.

--update

Whether to open an existing output dataset in update mode.

--upsert

Added in version 3.12.

Variant of *--append* where the *OGRLayer::UpsertFeature()* operation is used to insert or update features instead of appending with *OGRLayer::CreateFeature()*.

This is currently implemented only in a few drivers: *GPKG -- GeoPackage vector*, *Elasticsearch: Geographically Encoded Objects for Elasticsearch* and *MongoDBv3* (drivers that implement upsert expose the *GDAL_DCAP_UPSERT* capability).

The upsert operation uses the FID of the input feature, when it is set (and the FID column name is not the empty string), as the key to update existing features. It is crucial to make sure that the FID in the source and target layers are consistent.

For the GPKG driver, it is also possible to upsert features whose FID is unset or non-significant (the `--unset-fid` option of *gdal vector edit* can be used to ignore the FID from the source feature), when there is a UNIQUE column that is not the integer primary key.

-q, --quiet

Suppress progress bar and some warning messages.

Return status code

The program returns status code 0 in case of success, and non-zero in case of error (non-blocking errors emitted as warnings are considered as a successful execution).

Examples

Example 1: Converting file poly.shp to a GeoPackage

```
$ gdal vector convert poly.shp output.gpkg
```

Example 2: Add new layer from file line.shp to an existing GeoPackage, and rename it "lines"

```
$ gdal vector convert --update --output-layer=lines line.shp output.gpkg
```

Example 3: Append features from from file poly2.shp to an existing layer poly of a GeoPackage, without a progress bar

```
$ gdal vector convert --quiet --append --output-layer=poly poly2.shp output.gpkg
```

5.1.4.11 gdal vector convex-hull

Added in version 3.13.

Synopsis

```
Usage: gdal vector convex-hull [OPTIONS] <INPUT> <OUTPUT>

Compute the convex hull of geometries of a vector dataset.
```

↪repeated] [not available in pipelines]
  --upsert                                              Upsert features (implies 'append
↪') [not available in pipelines]
```

(continues on next page)

(continued from previous page)

```
                                                    Mutually exclusive with --append
```

Description

gdal vector convex-hull computes the smallest convex polygon that covers the input geometry. Generally the result will be a Polygon, but for degenerate inputs it may be a LineString or a Point.

This command can also be used as a step of *gdal vector pipeline*.

GDALG output (on-the-fly / streamed dataset)

This program supports serializing the command line as a JSON file using the `GDALG` output format. The resulting file can then be opened as a vector dataset using the *GDALG: GDAL Streamed Algorithm* driver, and apply the specified pipeline in a on-the-fly / streamed way.

> **Note**
>
> This command requires a GDAL build against the GEOS library.

Standard Options

--append

Whether appending features to existing layer(s) is allowed. This also creates the output dataset if it does not exist yet.

--active-layer <ACTIVE-LAYER>

Set the active layer. When it is specified, only the layer specified by its name will be subject to the processing. Other layers will be not modified. If this option is not specified, all layers will be subject to the processing.

--active-geometry <ACTIVE-GEOMETRY>

Set the active geometry field from its name. When it is specified, only the specified geometry field will be subject to the processing. Other geometry fields will be not modified. If this option is not specified, all geometry fields will be subject to the processing. This option can be combined together with `--active-layer`.

--co, --creation-option <NAME>=<VALUE>

Many formats have one or more optional dataset creation options that can be used to control particulars about the file created. For instance, the GeoPackage driver supports creation options to control the version.

May be repeated.

The dataset creation options available vary by format driver, and some simple formats have no creation options at all. A list of options supported for a format can be listed with the *--formats* command line option but the documentation for the format is the definitive source of information on driver creation options. See *Vector drivers* format specific documentation for legal creation options for each format.

Note that dataset creation options are different from layer creation options.

--if, --input-format <format>

Format/driver name to be attempted to open the input file(s). It is generally not necessary to specify it, but it can be used to skip automatic driver detection, when it fails to select the appropriate driver. This option can be repeated several times to specify several candidate drivers. Note that it does not force those drivers to open the dataset. In particular, some drivers have requirements on file extensions.

May be repeated.

--input-layer <INPUT-LAYER>

Specifies the name of one or more layers to process. By default, all layers will be processed. To read and write all layers but only process a subset, use *--active-layer*.

--lco, --layer-creation-option <NAME>=<VALUE>

Many formats have one or more optional layer creation options that can be used to control particulars about the layer created. For instance, the GeoPackage driver supports layer creation options to control the feature identifier or geometry column name, setting the identifier or description, etc.

May be repeated.

The layer creation options available vary by format driver, and some simple formats have no layer creation options at all. A list of options supported for a format can be listed with the *--formats* command line option but the documentation for the format is the definitive source of information on driver creation options. See *Vector drivers* format specific documentation for legal creation options for each format.

Note that layer creation options are different from dataset creation options.

--oo, --open-option <NAME>=<VALUE>

Dataset open option (format specific).

May be repeated.

-f, --of, --format, --output-format <OUTPUT-FORMAT>

Which output vector format to use. Allowed values may be given by `gdal --formats | grep vector | grep rw | sort`

--output-layer <NAME>

Specifies the name of the layer to which features will be written. If not specified, output layer names will be the same as input layer names.

--output-open-option, --output-oo <NAME>=<VALUE>

Added in version 3.12.

Dataset open option for output dataset (format specific).

May be repeated.

--overwrite

Allow program to overwrite existing target file or dataset. Otherwise, by default, **gdal** errors out if the target file or dataset already exists.

--overwrite-layer

Whether overwriting the existing output vector layer is allowed.

--skip-errors

Added in version 3.12.

Whether failures to write feature(s) should be ignored. Note that this option sets the size of the transaction unit to one feature at a time, which may cause severe slowdown when inserting into databases.

--update

Whether to open an existing output dataset in update mode.

--upsert

Added in version 3.12.

Variant of *--append* where the *OGRLayer::UpsertFeature()* operation is used to insert or update features instead of appending with *OGRLayer::CreateFeature()*.

This is currently implemented only in a few drivers: *GPKG -- GeoPackage vector*, *Elasticsearch: Geographically Encoded Objects for Elasticsearch* and *MongoDBv3* (drivers that implement upsert expose the *GDAL_DCAP_UPSERT* capability).

The upsert operation uses the FID of the input feature, when it is set (and the FID column name is not the empty string), as the key to update existing features. It is crucial to make sure that the FID in the source and target layers are consistent.

For the GPKG driver, it is also possible to upsert features whose FID is unset or non-significant (the `--unset-fid` option of *gdal vector edit* can be used to ignore the FID from the source feature), when there is a UNIQUE column that is not the integer primary key.

Examples

Example 1: Compute the convex hull of each country

```
gdal vector convex-hull countries.gpkg countries_convexhull.gpkg
```

Example 2: Compute the convex hull of city locations in each country

Here the Natural Earth Populated Places dataset is used. To ensure that a polygonal hull is generated for each country, the input points are first buffered by a small amount. Otherwise, countries having only one or two cities would end up with a point or line geometry.

```
gdal vector pipeline ! \
    read ne_10m_populated_places.shp ! \
    buffer 0.1 ! \
    combine --group-by ADM0_A3 ! \
    convex-hull ! \
    write country_city_hulls.gpkg
```

5.1.4.12 gdal vector create

Added in version 3.13.

Synopsis

```
Usage: gdal vector create [OPTIONS] <OUTPUT>

Create a vector dataset.

Positional arguments:

```

Description

gdal vector create creates one or more vector layers, creating the dataset if it doesn't exist or adding layers to an existing dataset if the underlying format supports it.

The layer fields, geometry type and coordinate reference system can be defined either by providing an existing dataset or an OGR_SCHEMA file/JSON as a template, or by explicitly specifying the various components.

gdal vector create can be used as the first step of a pipeline.

The following options are available:

Program-Specific Options

--output-layer <OUTPUT-LAYER>

Output layer name.

Only meaningful when creating a single layer dataset. It allows defining or overriding the name of the created layer.

-i, --like, --input <TEMPLATE-DATASET>

Vector dataset to use as a template for the created dataset.

If the template dataset contains multiple layers and the destination format does not support multiple layers the program will exit with an error unless *--input-layer* is used to specify which single layer from the input dataset should be used as a template.

Mutually exclusive with *--schema* and with *--field*, *--geometry-type*, *--geometry-field* and *--crs*.

--layer, --input-layer <INPUT-LAYER>

Layer(s) of the input dataset to use as a template for the created layer.

This option can be repeated multiple times to specify multiple layers.

This option is only meaningful when *--like* or *--schema* are used with an input dataset containing multiple layers.

--schema <OGR_SCHEMA>

File or JSON string containing the OGR_SCHEMA of the layer to create.

This can be a filename, a URL or JSON string conformant with the ogr_fields_override.schema.json schema

If the OGR_SCHEMA contains multiple layers and the destination format does not support multiple layers the program will exit with an error unless *--input-layer* is used to specify which single layer from the OGR_SCHEMA should be selected.

Mutually exclusive with *--like* and with *--field*, *--geometry-type*, *--geometry-field* and *--crs*.

--crs <CRS>

Defines the coordinate reference system of the created layer.

The coordinate reference systems that can be passed are anything supported by the *OGRSpatialReference::SetFromUserInput()* call, which includes EPSG Projected, Geographic or Compound CRS (i.e. EPSG:4296), a well known text (WKT) CRS definition, PROJ.4 declarations, or the name of a .prj file containing a WKT CRS definition.

Mutually exclusive with *--schema* and with *--like*.

--geometry-field <GEOMETRY-FIELD>

Name of the geometry field to create (if supported by the output format) (default: geom).

--geometry-type <GEOMETRY-TYPE>

Defines the geometry type of the created layer.

Layer geometry type to be one of `GEOMETRY`, `POINT`, `LINESTRING`, `POLYGON`, `MULTIPOINT`, `MULTILINESTRING`, `MULTIPOLYGON`, `GEOMETRYCOLLECTION`, `CURVE`, `CIRCULARSTRING`, `COMPOUNDCURVE`, `SURFACE`, `CURVEPOLYGON`, `MULTICURVE`, `MULTISURFACE`, `POLYHEDRALSURFACE` or `TIN`. `Z`, `M` or `ZM` suffixes can be appended to the above values to indicate the dimensionality.

Mutually exclusive with *--schema* and with *--like*.

--field <NAME>:<TYPE>[(,<WIDTH>[,<PRECISION>])]

Defines a field to be created in the layer.

This option can be repeated multiple times to create multiple fields.

The field type can be one of INTEGER, INTEGER64, REAL, STRING, DATE, TIME, DATETIME, BINARY, INTEGERLIST, REALLIST, STRINGLIST, INTEGER64LIST.

The width and precision can be specified for INTEGER, INTEGER64, REAL and STRING field types. For example, --field population:INTEGER(10,5) or --field name:STRING(255)

Mutually exclusive with *--schema* and with *--like*.

--fid <FID>

Defines the name of the Feature Identifier (FID) column, for drivers that support setting it (those which declare a FID layer creation option)

Mutually exclusive with *--schema* and with *--like*.

Standard Options

--oo, --open-option <NAME>=<VALUE>

Dataset open option (format specific).

May be repeated.

Return status code

The program returns status code 0 in case of success, and non-zero in case of error (non-blocking errors emitted as warnings are considered as a successful execution).

Examples

Example 1: Create a POINT layer named names with a string field named name in a new vector dataset

```
gdal vector create --geometry-type point  --crs EPSG:4326 --field name:string --output-
↪layer names points.gpkg
```

Example 2: Add a POINT layer named names2 with a string field named name to an existing vector dataset

```
gdal vector create --update --geometry-type point --crs EPSG:4326 --field name:string --
↪output-layer names2 points.gpkg
```

Example 3: Create a new vector dataset with a layer named countries_new based on the layer countries of an existing dataset

```
gdal vector create --like ../data/poly.gpkg --input-layer poly --output-layer areas_new␣
↪areas.gpkg
```

5.1.4.13 gdal vector dissolve

Added in version 3.13.

Synopsis

```
Usage: gdal vector dissolve [OPTIONS] <INPUT> <OUTPUT>

Dissolves multipart features

Positional arguments:
  -i, --input <INPUT>                                    Input vector datasets [required]␣
↪[not available in pipelines]
  -o, --output <OUTPUT>                                  Output vector dataset [required]␣
↪[not available in pipelines]

Common Options:
  -h, --help                                             Display help message and exit
  --json-usage                                           Display usage as JSON document␣
↪and exit
  --config <KEY>=<VALUE>                                 Configuration option [may be␣
↪repeated]
  -q, --quiet                                            Quiet mode (no progress bar or␣
↪warning message) [not available in pipelines]

Options:
  -l, --layer, --input-layer <INPUT-LAYER>               Input layer name(s) [may be␣
↪repeated] [not available in pipelines]
  -f, --of, --format, --output-format <OUTPUT-FORMAT>  Output format ("GDALG" allowed)␣
↪[not available in pipelines]
  --co, --creation-option <KEY>=<VALUE>                  Creation option [may be repeated]␣
↪[not available in pipelines]
  --lco, --layer-creation-option <KEY>=<VALUE>           Layer creation option [may be␣
↪repeated] [not available in pipelines]
  --overwrite                                            Whether overwriting existing␣
↪output dataset is allowed [not available in pipelines]
  --update                                               Whether to open existing dataset␣
↪in update mode [not available in pipelines]
  --overwrite-layer                                      Whether overwriting existing␣
↪output layer is allowed [not available in pipelines]
  --append                                               Whether appending to existing␣
↪layer is allowed [not available in pipelines]
                                                         Mutually exclusive with --upsert
  --output-layer <OUTPUT-LAYER>                          Output layer name [not available␣
↪in pipelines]
  --skip-errors                                          Skip errors when writing features␣
↪[not available in pipelines]
  --active-layer <ACTIVE-LAYER>                          Set active layer (if not␣
↪specified, all)
  --active-geometry <ACTIVE-GEOMETRY>                    Geometry field name to which to␣
↪restrict the processing (if not specified, all)

Advanced Options:
```

(continues on next page)

(continued from previous page)

```
  --if, --input-format <INPUT-FORMAT>                    Input formats [may be repeated]␣
↪[not available in pipelines]
  --oo, --open-option <KEY>=<VALUE>                      Open options [may be repeated]␣
↪[not available in pipelines]
  --output-oo, --output-open-option <KEY>=<VALUE>        Output open options [may be␣
↪repeated] [not available in pipelines]
  --upsert                                               Upsert features (implies 'append
↪') [not available in pipelines]
                                                         Mutually exclusive with --append
```

Description

gdal vector dissolve performs a union operation on the elements of each feature's geometry. This has the following effects:

- Duplicate vertices are eliminated.
- Nodes are added where input linework intersects.
- Polygons that overlap are "dissolved" into a single feature.

For linear geometries, the union step is followed by a line-merging step, where lines are merged at points that form an endpoint of exactly two lines.

To dissolve the geometries of multiple features together, first combine them into single features with *gdal vector combine*.

`dissolve` can be used as a step of *gdal vector pipeline*.

Standard Options

--append

Whether appending features to existing layer(s) is allowed. This also creates the output dataset if it does not exist yet.

--active-layer <ACTIVE-LAYER>

Set the active layer. When it is specified, only the layer specified by its name will be subject to the processing. Other layers will be not modified. If this option is not specified, all layers will be subject to the processing.

--active-geometry <ACTIVE-GEOMETRY>

Set the active geometry field from its name. When it is specified, only the specified geometry field will be subject to the processing. Other geometry fields will be not modified. If this option is not specified, all geometry fields will be subject to the processing. This option can be combined together with `--active-layer`.

--co, --creation-option <NAME>=<VALUE>

Many formats have one or more optional dataset creation options that can be used to control particulars about the file created. For instance, the GeoPackage driver supports creation options to control the version.

May be repeated.

The dataset creation options available vary by format driver, and some simple formats have no creation options at all. A list of options supported for a format can be listed with the *--formats* command line option but the documentation for the format is the definitive source of information on driver creation options. See *Vector drivers* format specific documentation for legal creation options for each format.

Note that dataset creation options are different from layer creation options.

--if, --input-format <format>

Format/driver name to be attempted to open the input file(s). It is generally not necessary to specify it, but it can be used to skip automatic driver detection, when it fails to select the appropriate driver. This option can be repeated several times to specify several candidate drivers. Note that it does not force those drivers to open the dataset. In particular, some drivers have requirements on file extensions.

May be repeated.

--lco, --layer-creation-option <NAME>=<VALUE>

Many formats have one or more optional layer creation options that can be used to control particulars about the layer created. For instance, the GeoPackage driver supports layer creation options to control the feature identifier or geometry column name, setting the identifier or description, etc.

May be repeated.

The layer creation options available vary by format driver, and some simple formats have no layer creation options at all. A list of options supported for a format can be listed with the *--formats* command line option but the documentation for the format is the definitive source of information on driver creation options. See *Vector drivers* format specific documentation for legal creation options for each format.

Note that layer creation options are different from dataset creation options.

--oo, --open-option <NAME>=<VALUE>

Dataset open option (format specific).

May be repeated.

-f, --of, --format, --output-format <OUTPUT-FORMAT>

Which output vector format to use. Allowed values may be given by `gdal --formats | grep vector | grep rw | sort`

--output-open-option, --output-oo <NAME>=<VALUE>

Added in version 3.12.

Dataset open option for output dataset (format specific).

May be repeated.

--overwrite

Allow program to overwrite existing target file or dataset. Otherwise, by default, **gdal** errors out if the target file or dataset already exists.

--overwrite-layer

Whether overwriting the existing output vector layer is allowed.

--skip-errors

Added in version 3.12.

Whether failures to write feature(s) should be ignored. Note that this option sets the size of the transaction unit to one feature at a time, which may cause severe slowdown when inserting into databases.

--update

Whether to open an existing output dataset in update mode.

--upsert

Added in version 3.12.

Variant of *--append* where the *OGRLayer::UpsertFeature()* operation is used to insert or update features instead of appending with *OGRLayer::CreateFeature()*.

This is currently implemented only in a few drivers: *GPKG -- GeoPackage vector*, *Elasticsearch: Geographically Encoded Objects for Elasticsearch* and *MongoDBv3* (drivers that implement upsert expose the *GDAL_DCAP_UPSERT* capability).

The upsert operation uses the FID of the input feature, when it is set (and the FID column name is not the empty string), as the key to update existing features. It is crucial to make sure that the FID in the source and target layers are consistent.

For the GPKG driver, it is also possible to upsert features whose FID is unset or non-significant (the `--unset-fid` option of *gdal vector edit* can be used to ignore the FID from the source feature), when there is a UNIQUE column that is not the integer primary key.

Return status code

The program returns status code 0 in case of success, and non-zero in case of error (non-blocking errors emitted as warnings are considered as a successful execution).

Examples

Example 1: Dissolve country boundaries into continent boundaries

```
gdal vector pipeline read countries.shp !
    combine --group-by CONTINENT ! \
    dissolve ! \
    write continents.shp
```

5.1.4.14 gdal vector edit

Added in version 3.11.

Synopsis

```
Usage: gdal vector edit [OPTIONS] <INPUT> <OUTPUT>

Edit metadata of a vector dataset.

Positional arguments:
  -i, --input <INPUT>                                    Input vector datasets [required]␣
↪[not available in pipelines]
  -o, --output <OUTPUT>                                  Output vector dataset [required]␣
↪[not available in pipelines]

Common Options:
  -h, --help                                             Display help message and exit
  --json-usage                                           Display usage as JSON document␣
↪and exit
  --config <KEY>=<VALUE>                                 Configuration option [may be␣
↪repeated]
  -q, --quiet                                            Quiet mode (no progress bar or␣
↪warning message) [not available in pipelines]

Options:
  -l, --layer, --input-layer <INPUT-LAYER>               Input layer name(s) [may be␣
↪repeated] [not available in pipelines]
```

(continues on next page)

(continued from previous page)

```
  -f, --of, --format, --output-format <OUTPUT-FORMAT>  Output format ("GDALG" allowed)␣

↪') [not available in pipelines]
                                                       Mutually exclusive with --append
```

Description

gdal vector edit can be used to edit metadata of a vector dataset: its CRS, the layer geometry type, dataset and layer metadata.

`edit` can also be used as a step of *gdal vector pipeline*.

Features are not modified.

GDALG output (on-the-fly / streamed dataset)

This program supports serializing the command line as a JSON file using the `GDALG` output format. The resulting file can then be opened as a vector dataset using the *GDALG: GDAL Streamed Algorithm* driver, and apply the specified pipeline in a on-the-fly / streamed way.

Program-Specific Options

--crs <CRS>

Override CRS, without reprojecting.

The coordinate reference systems that can be passed are anything supported by the *OGRSpatialReference::SetFromUserInput()* call, which includes EPSG Projected, Geographic or Compound CRS (i.e. EPSG:4296), a well known text (WKT) CRS definition, PROJ.4 declarations, or the name of a .prj file containing a WKT CRS definition.

`null` or `none` can be specified to unset an existing CRS.

--geometry-type <GEOMETRY-TYPE>

Change the layer geometry type to be one of `GEOMETRY`, `POINT`, `LINESTRING`, `POLYGON`, `MULTIPOINT`, `MULTILINESTRING`, `MULTIPOLYGON`, `GEOMETRYCOLLECTION`, `CURVE`, `CIRCULARSTRING`, `COMPOUNDCURVE`, `SURFACE`, `CURVEPOLYGON`, `MULTICURVE`, `MULTISURFACE`, `POLYHEDRALSURFACE` or `TIN`. `Z`, `M` or `ZM` suffixes can be appended to the above values to indicate the dimensionality. Note that feature geometries themselves are not modified. Thus this option can be used to fix an inappropriate geometry type at the layer level.

--layer-metadata <KEY>=<VALUE>

Add/update metadata item, at the layer level.

--metadata <KEY>=<VALUE>

Add/update metadata item, at the dataset level.

--unset-fid

Added in version 3.12.

Can be specified to prevent the name of the source FID column and source feature IDs from being reused for the target layer. This option can for example be useful if selecting source features with a ORDER BY clause.

--unset-metadata <KEY>

Remove metadata item, at the dataset level.

--unset-layer-metadata <KEY>

Remove metadata item, at the layer level.

Standard Options

--active-layer <ACTIVE-LAYER>

Set the active layer. When it is specified, only the layer specified by its name will be subject to the processing. Other layers will be not modified. If this option is not specified, all layers will be subject to the processing.

--append

Whether appending features to existing layer(s) is allowed. This also creates the output dataset if it does not exist yet.

--co, --creation-option <NAME>=<VALUE>

Many formats have one or more optional dataset creation options that can be used to control particulars about the file created. For instance, the GeoPackage driver supports creation options to control the version.

May be repeated.

The dataset creation options available vary by format driver, and some simple formats have no creation options at all. A list of options supported for a format can be listed with the *--formats* command line option but the documentation for the format is the definitive source of information on driver creation options. See *Vector drivers* format specific documentation for legal creation options for each format.

Note that dataset creation options are different from layer creation options.

--if, --input-format <format>

Format/driver name to be attempted to open the input file(s). It is generally not necessary to specify it, but it can be used to skip automatic driver detection, when it fails to select the appropriate driver. This option can be repeated several times to specify several candidate drivers. Note that it does not force those drivers to open the dataset. In particular, some drivers have requirements on file extensions.

May be repeated.

--input-layer <INPUT-LAYER>

Specifies the name of one or more layers to process. By default, all layers will be processed. To read and write all layers but only process a subset, use `--active-layer`.

--lco, --layer-creation-option <NAME>=<VALUE>

Many formats have one or more optional layer creation options that can be used to control particulars about the layer created. For instance, the GeoPackage driver supports layer creation options to control the feature identifier or geometry column name, setting the identifier or description, etc.

May be repeated.

The layer creation options available vary by format driver, and some simple formats have no layer creation options at all. A list of options supported for a format can be listed with the *--formats* command line option but the documentation for the format is the definitive source of information on driver creation options. See *Vector drivers* format specific documentation for legal creation options for each format.

Note that layer creation options are different from dataset creation options.

--oo, --open-option <NAME>=<VALUE>

Dataset open option (format specific).

May be repeated.

-f, --of, --format, --output-format <OUTPUT-FORMAT>

Which output vector format to use. Allowed values may be given by `gdal --formats | grep vector | grep rw | sort`

--output-layer <NAME>

Specifies the name of the layer to which features will be written. If not specified, output layer names will be the same as input layer names.

--output-open-option, --output-oo <NAME>=<VALUE>

Added in version 3.12.

Dataset open option for output dataset (format specific).

May be repeated.

--overwrite

Allow program to overwrite existing target file or dataset. Otherwise, by default, **gdal** errors out if the target file or dataset already exists.

--overwrite-layer

Whether overwriting the existing output vector layer is allowed.

--skip-errors

Added in version 3.12.

Whether failures to write feature(s) should be ignored. Note that this option sets the size of the transaction unit to one feature at a time, which may cause severe slowdown when inserting into databases.

--update

Whether to open an existing output dataset in update mode.

--upsert

Added in version 3.12.

Variant of *--append* where the *OGRLayer::UpsertFeature()* operation is used to insert or update features instead of appending with *OGRLayer::CreateFeature()*.

This is currently implemented only in a few drivers: *GPKG -- GeoPackage vector*, *Elasticsearch: Geographically Encoded Objects for Elasticsearch* and *MongoDBv3* (drivers that implement upsert expose the *GDAL_DCAP_UPSERT* capability).

The upsert operation uses the FID of the input feature, when it is set (and the FID column name is not the empty string), as the key to update existing features. It is crucial to make sure that the FID in the source and target layers are consistent.

For the GPKG driver, it is also possible to upsert features whose FID is unset or non-significant (the `--unset-fid` option of *gdal vector edit* can be used to ignore the FID from the source feature), when there is a UNIQUE column that is not the integer primary key.

Return status code

The program returns status code 0 in case of success, and non-zero in case of error (non-blocking errors emitted as warnings are considered as a successful execution).

Examples

Example 1: Change the CRS of a GeoPackage file (without reprojecting it) and its geometry type

```
$ gdal vector edit --crs=EPSG:4326 --geometry-type=POLYGONZM in.gpkg out.gpkg --overwrite
```

Example 2: Apply a CRS to a Shapefile

If a Shapefile is missing its associated `.prj` file, it can be created as follows:

```
$ gdal vector edit --crs=EPSG:3857 in.shp out.shp
```

5.1.4.15 gdal vector filter

Added in version 3.11.

Synopsis

```
Usage: gdal vector filter [OPTIONS] <INPUT> <OUTPUT>

Filter a vector dataset.

Positional arguments:

↪') [not available in pipelines]
                                                          Mutually exclusive with --append
```

Description

gdal vector filter can be used to filter a vector dataset from their spatial extent or a SQL WHERE clause.

`filter` can also be used as a step of *gdal vector pipeline*.

GDALG output (on-the-fly / streamed dataset)

This program supports serializing the command line as a JSON file using the `GDALG` output format. The resulting file can then be opened as a vector dataset using the *GDALG: GDAL Streamed Algorithm* driver, and apply the specified pipeline in a on-the-fly / streamed way.

Program-Specific Options

--bbox `<xmin>,<ymin>,<xmax>,<ymax>`

Bounds to which to filter the dataset. They are assumed to be in the CRS of the input dataset. The X and Y axis are the "GIS friendly ones", that is X is longitude or easting, and Y is latitude or northing. Note that filtering does not clip geometries to the bounding box.

--update-extent

Update layer extent to take into account the filter(s). Otherwise the layer extent will generally be the one of the source layer before applying the filter(s). Note that using this option requires doing a full scan of the filtered layers.

--where `<WHERE>|@<filename>`

Attribute query (like SQL WHERE).

Standard Options

--active-layer `<ACTIVE-LAYER>`

Set the active layer. When it is specified, only the layer specified by its name will be subject to the processing. Other layers will be not modified. If this option is not specified, all layers will be subject to the processing.

--append

Whether appending features to existing layer(s) is allowed. This also creates the output dataset if it does not exist yet.

--co, --creation-option `<NAME>=<VALUE>`

Many formats have one or more optional dataset creation options that can be used to control particulars about the file created. For instance, the GeoPackage driver supports creation options to control the version.

May be repeated.

The dataset creation options available vary by format driver, and some simple formats have no creation options at all. A list of options supported for a format can be listed with the *--formats* command line option but the documentation for the format is the definitive source of information on driver creation options. See *Vector drivers* format specific documentation for legal creation options for each format.

Note that dataset creation options are different from layer creation options.

--if, --input-format <format>

Format/driver name to be attempted to open the input file(s). It is generally not necessary to specify it, but it can be used to skip automatic driver detection, when it fails to select the appropriate driver. This option can be repeated several times to specify several candidate drivers. Note that it does not force those drivers to open the dataset. In particular, some drivers have requirements on file extensions.

May be repeated.

--input-layer <INPUT-LAYER>

Specifies the name of one or more layers to process. By default, all layers will be processed. To read and write all layers but only process a subset, use *--active-layer*.

--lco, --layer-creation-option <NAME>=<VALUE>

Many formats have one or more optional layer creation options that can be used to control particulars about the layer created. For instance, the GeoPackage driver supports layer creation options to control the feature identifier or geometry column name, setting the identifier or description, etc.

May be repeated.

The layer creation options available vary by format driver, and some simple formats have no layer creation options at all. A list of options supported for a format can be listed with the *--formats* command line option but the documentation for the format is the definitive source of information on driver creation options. See *Vector drivers* format specific documentation for legal creation options for each format.

Note that layer creation options are different from dataset creation options.

--oo, --open-option <NAME>=<VALUE>

Dataset open option (format specific).

May be repeated.

-f, --of, --format, --output-format <OUTPUT-FORMAT>

Which output vector format to use. Allowed values may be given by `gdal --formats | grep vector | grep rw | sort`

--output-layer <NAME>

Specifies the name of the layer to which features will be written. If not specified, output layer names will be the same as input layer names.

--output-open-option, --output-oo <NAME>=<VALUE>

Added in version 3.12.

Dataset open option for output dataset (format specific).

May be repeated.

--overwrite

Allow program to overwrite existing target file or dataset. Otherwise, by default, **gdal** errors out if the target file or dataset already exists.

--overwrite-layer

Whether overwriting the existing output vector layer is allowed.

--skip-errors

Added in version 3.12.

Whether failures to write feature(s) should be ignored. Note that this option sets the size of the transaction unit to one feature at a time, which may cause severe slowdown when inserting into databases.

--update

Whether to open an existing output dataset in update mode.

--upsert

Added in version 3.12.

Variant of *--append* where the *OGRLayer::UpsertFeature()* operation is used to insert or update features instead of appending with *OGRLayer::CreateFeature()*.

This is currently implemented only in a few drivers: *GPKG -- GeoPackage vector*, *Elasticsearch: Geographically Encoded Objects for Elasticsearch* and *MongoDBv3* (drivers that implement upsert expose the *GDAL_DCAP_UPSERT* capability).

The upsert operation uses the FID of the input feature, when it is set (and the FID column name is not the empty string), as the key to update existing features. It is crucial to make sure that the FID in the source and target layers are consistent.

For the GPKG driver, it is also possible to upsert features whose FID is unset or non-significant (the `--unset-fid` option of *gdal vector edit* can be used to ignore the FID from the source feature), when there is a UNIQUE column that is not the integer primary key.

Return status code

The program returns status code 0 in case of success, and non-zero in case of error (non-blocking errors emitted as warnings are considered as a successful execution).

Examples

Example 1: Select features from a GeoPackage file that intersect the bounding box from longitude 2, latitude 49, to longitude 3, latitude 50 in WGS 84

```
$ gdal vector filter --bbox=2,49,3,50 in.gpkg out.gpkg --overwrite
```

Example 2: Filter Shapefile features with an attribute query

Bash

PowerShell

```
gdal vector pipeline \
    ! read in.shp \
    ! filter --where "CODE IS NULL AND NAME NOT LIKE 'TEMP%'" \
    ! write out.gpkg
```

```
gdal vector pipeline `
    ! read in.shp `
    ! filter --where "CODE IS NULL AND NAME NOT LIKE 'TEMP%'" `
    ! write out.gpkg
```

5.1.4.16 gdal vector info

Added in version 3.11.

Synopsis

```
Usage: gdal vector info [OPTIONS] <INPUT>...

Return information on a vector dataset.

Positional arguments:
  -i, --dataset, --input <INPUT>                      Input vector datasets [may be␣
↪repeated] [required]

Common Options:
  -h, --help                                          Display help message and exit
  --json-usage                                        Display usage as JSON document␣
↪and exit
  --config <KEY>=<VALUE>                              Configuration option [may be␣
↪repeated]

Options:
  -f, --of, --format, --output-format <OUTPUT-FORMAT>  Output format. OUTPUT-
↪FORMAT=json|text
  -l, --layer, --input-layer <INPUT-LAYER>            Input layer name [may be repeated]
                                                      Mutually exclusive with --sql, --
↪fid
  --features                                          List all features (beware of RAM␣
↪consumption on large layers)
                                                      Mutually exclusive with --summary
  --summary                                           List the layer names and the␣
↪geometry type
                                                      Mutually exclusive with --features

  --if, --input-format <INPUT-FORMAT>                 Input formats [may be repeated]

Esoteric Options:
  --crs-format <CRS-FORMAT>                           Which format to use to report CRS.
↪ CRS-FORMAT=AUTO|WKT2|PROJJSON (default: AUTO)
```

Description

gdal vector info lists various information about a GDAL supported vector dataset, and returns them on the standard output stream when used from the command line, or in the `output` parameter when used from the API.

Starting with GDAL 3.12, **gdal vector info** can be used as the last step of a pipeline.

The following options are available:

Program-Specific Options

--dialect <dialect>

SQL dialect. In some cases can be used to use (unoptimized) *OGR SQL dialect* instead of the native SQL of an RDBMS by passing the `OGRSQL` dialect value. The *SQL SQLite dialect* can be selected with the `SQLITE` and `INDIRECT_SQLITE` dialect values, and this can be used with any datasource.

--features

List all features by default, unless limited with *--limit*. Beware of RAM consumption on large layers when using JSON output. This option is mutually exclusive with the *--summary* option.

-f, --of, --format, --output-format `json|text`

Which output format to use. Default is JSON, and starting with GDAL 3.12, text when invoked from command line.

-l, --layer, --input-layer <INPUT-LAYER>

Name of one or more layers to inspect. If no layer names are passed and *--sql* is not specified, then all layers will be selected.

--limit <FEATURE-COUNT>

Added in version 3.12.

Limit the number of features reported per layer. When set, this implies *--features*.

--sql <statement>|@<filename>

Execute the indicated SQL statement and return the result. The `@<filename>` syntax can be used to indicate that the content is in the pointed filename (e.g `@my_select.txt` where my_select.txt is a file in the current directory). Data can also be edited with SQL INSERT, UPDATE, DELETE, DROP TABLE, ALTER TABLE etc if the dataset is opened in update mode. Editing capabilities depend on the selected dialect with *--dialect*.

This option is mutually exclusive with the *--where* option.

--summary

Print a summary with the list of layers and the geometry type of each layer. This option is mutually exclusive with the *--features* option.

--where <WHERE>|@<filename>

An attribute query in a restricted form of the queries used in the SQL *WHERE* statement. Only features matching the attribute query will be reported. The `@<filename>` syntax can be used to indicate that the content is in the pointed filename.

Example of `--where` and quoting:

```
--where "\"Corner Point Identifier\" LIKE '%__00_00'"
```

This option is mutually exclusive with the *--sql* option.

--fid <FID>

Added in version 3.13.

Feature identifier. Only the feature with the specified FID will be reported.

--crs-format AUTO|WKT2|PROJJSON

Added in version 3.13.

Which format to use to report the CRS. In AUTO default mode, if the CRS can be captured with an authority name and code (known of PROJ), only a summary of the CRS, including its name, ID, type and area of use will be reported. Otherwise a full WKT2:2019 definition will be reported.

> **Note**
>
> *--crs-format* can only be set when *--output-format* is set to `text`. The JSON text format includes both WKT2 and PROJJSON.

Standard Options

--oo, --open-option <NAME>=<VALUE>

Dataset open option (format specific).

May be repeated.

--if, --input-format <format>

Format/driver name to be attempted to open the input file(s). It is generally not necessary to specify it, but it can be used to skip automatic driver detection, when it fails to select the appropriate driver. This option can be repeated several times to specify several candidate drivers. Note that it does not force those drivers to open the dataset. In particular, some drivers have requirements on file extensions.

May be repeated.

Return status code

The program returns status code 0 in case of success, and non-zero in case of error (non-blocking errors emitted as warnings are considered as a successful execution).

Examples

Example 1: Getting information on the file poly.gpkg (with text output), listing all features

```
$ gdal vector info --features poly.gpkg
INFO: Open of `poly.gpkg'
      using driver `GPKG' successful.

Layer name: poly

```

Example 3: List all layers in a dataset using jq

```
gdal vector info av_2056.gpkg --format json | jq ".layers[].name"
```

Example 4: List all layers and their geometry fields using jq

Bash

PowerShell

```
$ gdal vector info counties-albers-10m.gpkg --output-format=JSON | jq -r '
  .layers[]
  | .name as $layer
  | .geometryFields[]?
  | "\($layer): \(.name) (\(.type))"'
```

```
gdal vector info counties-albers-10m.gpkg --output-format=JSON | jq -r '
  .layers[]
  | .name as $layer
  | .geometryFields[]?
  | \"\($layer): \(.name) (\(.type))\"'
```

returns:

```
counties: geom (Geometry)
states: geom (MultiPolygon)
nation: geom (MultiPolygon)
```

5.1.4.17 gdal vector export-schema

Added in version 3.13.

Synopsis

```
Usage: gdal vector export-schema [OPTIONS] <INPUT>...

Export the OGR_SCHEMA from a vector dataset.

Positional arguments:
  -i, --dataset, --input <INPUT>            Input vector datasets [may be repeated]␣
↪[required]

Common Options:
  -h, --help                                Display help message and exit
  --json-usage                              Display usage as JSON document and exit
  --config <KEY>=<VALUE>                    Configuration option [may be repeated]

Options:
  -l, --layer, --input-layer <INPUT-LAYER>  Input layer name [may be repeated]
  -o, --output <OUTPUT>                     Output file name. If not specified, output␣
↪is sent to stdout
  --overwrite                               Whether overwriting existing output file is␣
↪allowed

Advanced Options:
  --oo, --open-option <KEY>=<VALUE>         Open options [may be repeated]
  --if, --input-format <INPUT-FORMAT>       Input formats [may be repeated]
```

Description

gdal vector export-schema exports the OGR_SCHEMA from a GDAL-supported vector dataset, and returns it on the standard output stream when used from the command line, or in the output parameter when used from the API.

OGR_SCHEMA is a JSON object describing the structure of a vector dataset according to the schema definition at ogr_fields_override.schema.json

gdal vector export-schema can be used as the last step of a pipeline.

The following options are available:

Program-Specific Options

-l, --layer, --input-layer <INPUT-LAYER>

Name of one or more layers to inspect. If no layer names are passed, then all layers will be selected.

Standard Options

-o, --output <OUTPUT>

Added in version 3.14.

Filename to write the OGR_SCHEMA. If not specified, the output will be written to the standard output stream.

--oo, --open-option <NAME>=<VALUE>

Dataset open option (format specific).

May be repeated.

--if, --input-format <format>

Format/driver name to be attempted to open the input file(s). It is generally not necessary to specify it, but it can be used to skip automatic driver detection, when it fails to select the appropriate driver. This option can be repeated several times to specify several candidate drivers. Note that it does not force those drivers to open the dataset. In particular, some drivers have requirements on file extensions.

May be repeated.

--overwrite

Allow program to overwrite existing target file or dataset. Otherwise, by default, **gdal** errors out if the target file or dataset already exists.

Return status code

The program returns status code 0 in case of success, and non-zero in case of error (non-blocking errors emitted as warnings are considered as a successful execution).

Examples

Example 1: Extracting the OGR_SCHEMA from the file poly.gpkg

```
gdal vector export-schema poly.gpkg
```

Example 2: Save the OGR_SCHEMA to a file

When using Windows PowerShell 5.1, redirecting output with > or `Out-File -Encoding utf8` produces UTF-8 with a BOM (Byte Order Mark). When the schema is read by *gdal vector create*, this may result in `ERROR 1: JSON parsing error: unexpected character (at offset 0)`.

To avoid encoding issues, write the file using the *--output* option.

Bash

PowerShell

```
gdal vector export-schema natural_earth_vector.gpkg --layer "ne_50m_admin_0_countries" >␣
↪countries.json
```

```
# PowerShell (all versions)
gdal vector export-schema natural_earth_vector.gpkg --layer "ne_50m_admin_0_countries" --
↪output countries.json --overwrite

# PowerShell 7+ only
gdal vector export-schema natural_earth_vector.gpkg --layer "ne_50m_admin_0_countries" |␣
↪Out-File countries.json -Encoding utf8
```

Example 3: Validate an OGR_SCHEMA file using Python

Validate against the latest version of the schema definition at ogr_fields_override.schema.json using the Python package check-jsonschema available on PyPI.

```
$ pip install check-jsonschema
$ check-jsonschema --schemafile https://raw.githubusercontent.com/OSGeo/gdal/master/ogr/
↪data/ogr_fields_override.schema.json countries.json --verbose
```

Example 4: Create an OGR_SCHEMA at the end of a pipeline

This example renames the field `pop_est` to `estimated_population` and changes its type from `Real` to `Integer`, before exporting the resulting OGR_SCHEMA.

Bash

PowerShell

```
gdal vector pipeline \
    ! read natural_earth_vector.gpkg --layer ne_50m_admin_0_countries \
    ! sql --sql "SELECT geom,name,abbrev,pop_est AS estimated_population FROM ne_50m_
↪admin_0_countries" --output-layer "countries" \
    ! set-field-type --field-name "estimated_population" --field-type Integer \
    ! export-schema --output countries-population.json
```

```
gdal vector pipeline `
    ! read natural_earth_vector.gpkg --layer ne_50m_admin_0_countries `
    ! sql --sql "SELECT geom,name,abbrev,pop_est AS estimated_population FROM ne_50m_
↪admin_0_countries" --output-layer "countries" `
    ! set-field-type --field-name "estimated_population" --field-type Integer `
    ! export-schema --output countries-population.json
```

5.1.4.18 gdal vector explode-collections

Added in version 3.12.

Synopsis

```
Usage: gdal vector explode-collections [OPTIONS] <INPUT> <OUTPUT>

Explode geometries of type collection of a vector dataset.

Positional arguments:
  -i, --input <INPUT>                                    Input vector datasets [required]␣
↪[not available in pipelines]
  -o, --output <OUTPUT>                                  Output vector dataset [required]␣
↪[not available in pipelines]

Common Options:
  -h, --help                                             Display help message and exit
  --json-usage                                           Display usage as JSON document␣
↪and exit
  --config <KEY>=<VALUE>                                 Configuration option [may be␣
↪repeated]
```

(continues on next page)

(continued from previous page)

```
  -q, --quiet                                           Quiet mode (no progress bar or␣
↪warning message) [not available in pipelines]

Options:
  -l, --layer, --input-layer <INPUT-LAYER>              Input layer name(s) [may be␣
↪repeated] [not available in pipelines]
  -f, --of, --format, --output-format <OUTPUT-FORMAT>   Output format ("GDALG" allowed)␣
↪[not available in pipelines]
  --co, --creation-option <KEY>=<VALUE>                 Creation option [may be repeated]␣
↪[not available in pipelines]
  --lco, --layer-creation-option <KEY>=<VALUE>          Layer creation option [may be␣
↪repeated] [not available in pipelines]
  --overwrite                                           Whether overwriting existing␣
↪output dataset is allowed [not available in pipelines]
  --update                                              Whether to open existing dataset␣
↪in update mode [not available in pipelines]
  --overwrite-layer                                     Whether overwriting existing␣
↪output layer is allowed [not available in pipelines]
  --append                                              Whether appending to existing␣
↪layer is allowed [not available in pipelines]
                                                        Mutually exclusive with --upsert
  --output-layer <OUTPUT-LAYER>                         Output layer name [not available␣
↪in pipelines]
  --skip-errors                                         Skip errors when writing features␣
↪[not available in pipelines]
  --active-layer <ACTIVE-LAYER>                         Set active layer (if not␣
↪specified, all)
  --active-geometry <ACTIVE-GEOMETRY>                   Geometry field name to which to␣
↪restrict the processing (if not specified, all)
  --geometry-type <GEOMETRY-TYPE>                       Geometry type
  --skip-on-type-mismatch                               Skip feature when change of␣
↪feature geometry type failed

Advanced Options:
  --if, --input-format <INPUT-FORMAT>                   Input formats [may be repeated]␣
↪[not available in pipelines]
  --oo, --open-option <KEY>=<VALUE>                     Open options [may be repeated]␣
↪[not available in pipelines]
  --output-oo, --output-open-option <KEY>=<VALUE>       Output open options [may be␣
↪repeated] [not available in pipelines]
  --upsert                                              Upsert features (implies 'append
↪') [not available in pipelines]
                                                        Mutually exclusive with --append
```

Description

gdal vector explode-collections produces one feature for each geometry in any kind of geometry collection.

For example if a feature contains a geometry `MULTIPOINT(1 2,3 4)`, two corresponding target features will be generated: one with a geometry `POINT(1 2)` and another one with geometry `POINT(3 4)`. Note that collections are not recursively exploded, i.e. `GEOMETRYCOLLECTION(GEOMETRYCOLLECTION(POINT (1 2),POINT(3 4))` will be exploded as `GEOMETRYCOLLECTION(POINT (1 2),POINT(3 4))`.

It can also be used as a step of *gdal vector pipeline*.

GDALG output (on-the-fly / streamed dataset)

This program supports serializing the command line as a JSON file using the `GDALG` output format. The resulting file can then be opened as a vector dataset using the *GDALG: GDAL Streamed Algorithm* driver, and apply the specified pipeline in a on-the-fly / streamed way.

Program-Specific Options

--geometry-type <GEOMETRY-TYPE>

Change the geometry type of exploded geometries to be one of `GEOMETRY`, `POINT`, `LINESTRING`, `POLYGON`, `CIRCULARSTRING`, `COMPOUNDCURVE`, `CURVEPOLYGON`, `POLYHEDRALSURFACE` or `TIN`. `Z`, `M` or `ZM` suffixes can be appended to the above values to indicate the dimensionality. The presence of geometries that cannot be coerced to the specified type will cause an error, unless *--skip-on-type-mismatch* is specified.

--skip-on-type-mismatch

Do not generate output features when their target geometry type does not match the one specified by *--geometry-type*.

Standard Options

--active-geometry <ACTIVE-GEOMETRY>

Set the active geometry field from its name. When it is specified, only the specified geometry field will be subject to the processing. Other geometry fields will be not modified. If this option is not specified, all geometry fields will be subject to the processing. This option can be combined together with *--active-layer*.

--active-layer <ACTIVE-LAYER>

Set the active layer. When it is specified, only the layer specified by its name will be subject to the processing. Other layers will be not modified. If this option is not specified, all layers will be subject to the processing.

--append

Whether appending features to existing layer(s) is allowed. This also creates the output dataset if it does not exist yet.

--co, --creation-option <NAME>=<VALUE>

Many formats have one or more optional dataset creation options that can be used to control particulars about the file created. For instance, the GeoPackage driver supports creation options to control the version.

May be repeated.

The dataset creation options available vary by format driver, and some simple formats have no creation options at all. A list of options supported for a format can be listed with the *--formats* command line option but the documentation for the format is the definitive source of information on driver creation options. See *Vector drivers* format specific documentation for legal creation options for each format.

Note that dataset creation options are different from layer creation options.

--if, --input-format <format>

Format/driver name to be attempted to open the input file(s). It is generally not necessary to specify it, but it can be used to skip automatic driver detection, when it fails to select the appropriate driver. This option can be repeated several times to specify several candidate drivers. Note that it does not force those drivers to open the dataset. In particular, some drivers have requirements on file extensions.

May be repeated.

--input-layer <INPUT-LAYER>

Specifies the name of one or more layers to process. By default, all layers will be processed. To read and write all layers but only process a subset, use *--active-layer*.

--lco, --layer-creation-option <NAME>=<VALUE>

Many formats have one or more optional layer creation options that can be used to control particulars about the layer created. For instance, the GeoPackage driver supports layer creation options to control the feature identifier or geometry column name, setting the identifier or description, etc.

May be repeated.

The layer creation options available vary by format driver, and some simple formats have no layer creation options at all. A list of options supported for a format can be listed with the *--formats* command line option but the documentation for the format is the definitive source of information on driver creation options. See *Vector drivers* format specific documentation for legal creation options for each format.

Note that layer creation options are different from dataset creation options.

--oo, --open-option <NAME>=<VALUE>

Dataset open option (format specific).

May be repeated.

-f, --of, --format, --output-format <OUTPUT-FORMAT>

Which output vector format to use. Allowed values may be given by `gdal --formats | grep vector | grep rw | sort`

--output-layer <NAME>

Specifies the name of the layer to which features will be written. If not specified, output layer names will be the same as input layer names.

--output-open-option, --output-oo <NAME>=<VALUE>

Added in version 3.12.

Dataset open option for output dataset (format specific).

May be repeated.

--overwrite

Allow program to overwrite existing target file or dataset. Otherwise, by default, **gdal** errors out if the target file or dataset already exists.

--overwrite-layer

Whether overwriting the existing output vector layer is allowed.

--skip-errors

Added in version 3.12.

Whether failures to write feature(s) should be ignored. Note that this option sets the size of the transaction unit to one feature at a time, which may cause severe slowdown when inserting into databases.

--update

Whether to open an existing output dataset in update mode.

--upsert

Added in version 3.12.

Variant of *--append* where the *OGRLayer::UpsertFeature()* operation is used to insert or update features instead of appending with *OGRLayer::CreateFeature()*.

This is currently implemented only in a few drivers: *GPKG -- GeoPackage vector*, *Elasticsearch: Geographically Encoded Objects for Elasticsearch* and *MongoDBv3* (drivers that implement upsert expose the *GDAL_DCAP_UPSERT* capability).

The upsert operation uses the FID of the input feature, when it is set (and the FID column name is not the empty string), as the key to update existing features. It is crucial to make sure that the FID in the source and target layers are consistent.

For the GPKG driver, it is also possible to upsert features whose FID is unset or non-significant (the `--unset-fid` option of *gdal vector edit* can be used to ignore the FID from the source feature), when there is a UNIQUE column that is not the integer primary key.

Return status code

The program returns status code 0 in case of success, and non-zero in case of error (non-blocking errors emitted as warnings are considered as a successful execution).

Examples

Example 1: Only retain parts of geometry collections that are of type Point.

```
$ gdal vector explode-collections --geometry-type=POINT --skip-on-type-mismatch in.gpkg␣
↪points.shp --overwrite
```

5.1.4.19 gdal vector grid

Added in version 3.11.

Synopsis

```
Usage: gdal vector grid <SUBCOMMAND> [OPTIONS]

Common Options:
  -h, --help              Display help message and exit
  --json-usage            Display usage as JSON document and exit
  --config <KEY>=<VALUE>  Configuration option [may be repeated]
```

Description

This program creates a regular grid (raster) from the scattered data read from a vector dataset. Input data will be interpolated to fill grid nodes with values, you can choose from various interpolation methods.

It is possible to set the *GDAL_NUM_THREADS* configuration option to parallelize the processing. The value to specify is the number of worker threads, or `ALL_CPUS` to use all the cores/CPUs of the computer.

Since GDAL 3.12, this algorithm can be part of a *gdal pipeline*.

Options common to all algorithms

Standard options

-f, --of, --format, --output-format <OUTPUT-FORMAT>

Which output raster format to use. Allowed values may be given by `gdal --formats | grep raster | grep + | sort`

--co, --creation-option <NAME>=<VALUE>

Many formats have one or more optional dataset creation options that can be used to control particulars about the file created. For instance, the GeoPackage driver supports creation options to control the version.

May be repeated.

The dataset creation options available vary by format driver, and some simple formats have no creation options at all. A list of options supported for a format can be listed with the *--formats* command line option but the documentation for the format is the definitive source of information on driver creation options. See *Vector drivers* format specific documentation for legal creation options for each format.

Note that dataset creation options are different from layer creation options.

--overwrite

Allow program to overwrite existing target file or dataset. Otherwise, by default, **gdal** errors out if the target file or dataset already exists.

-l, --layer, --layer-name <LAYER-NAME>

Indicates the layer(s) from the datasource that will be used for input features. May be specified multiple times

--sql <SQL>|@<filename>

An SQL statement to be evaluated against the datasource to produce a virtual layer of features to be burned in. The @filename syntax can be used to indicate that the content is in the pointed filename.

--extent <xmin>,<ymin>,<xmax>,<ymax>

Set georeferenced extents. The values must be expressed in georeferenced units. If not specified, the extent of the output file will be the extent of the vector layers.

--resolution <xres>,<yres>

Set target resolution. The values must be expressed in georeferenced units. Both must be positive values. Note that *--resolution* cannot be used with *--size*.

--size <xsize>,<ysize>

Set output file size in pixels and lines. Note that *--size* cannot be used with *--resolution*.

--ot, --datatype, --output-data-type <OUTPUT-DATA-TYPE>

Force the output bands to be of the indicated data type. Defaults to `Float64`.

--crs <CRS>

Override the projection for the output file. If not specified, the projection of the input vector file will be used if available. When using this option, no reprojection of features from the CRS of the input vector to the specified CRS of the output raster, so use only this option to correct an invalid source CRS. The <CRS> may be any of the usual GDAL/OGR forms, complete WKT, PROJ.4, EPSG:n or a file containing the WKT.

--bbox <xmin>,<ymin>,<xmax>,<ymax>

Select only points contained within the specified bounding box.

--zfield <field_name>

Identifies an attribute field on the features to be used to get a Z value from. This value overrides the Z value read from the feature geometry record (naturally, if you have a Z value in the geometry, otherwise you have no choice and should specify a field name containing a Z value).

--zincrease <increase_value>

Addition to the attribute field on the features to be used to get a Z value from. The addition should be the same unit as the Z value. The result value will be Z value + Z increase value. The default value is 0.

--zmultiply <multiply_value>

This is multiplication ratio for the Z field. This can be used for a shift from e.g. feet to meters or from elevation to depth. The result value will be (Z value + Z increase value) * Z multiply value. The default value is 1.

Advanced options

--oo, --open-option <NAME>=<VALUE>

Dataset open option (format specific).

May be repeated.

--if, --input-format <format>

Format/driver name to be attempted to open the input file(s). It is generally not necessary to specify it, but it can be used to skip automatic driver detection, when it fails to select the appropriate driver. This option can be repeated several times to specify several candidate drivers. Note that it does not force those drivers to open the dataset. In particular, some drivers have requirements on file extensions.

May be repeated.

"invdist" algorithm

Interpolation using an inverse distance to a power.

When *--min-points-per-quadrant* or *--max-points-per-quadrant* is specified, the actual algorithm used is "invdistnn".

Options

--power <val>

Weighting power (default 2.0).

--smoothing <val>

Smoothing parameter (default 0.0).

--radius <val>

Set first and second radius (mutually exclusive with *--radius1* and *--radius2*. By default, uses the whole point array.

--radius1 <val>

The first radius (X axis if rotation angle is 0) of the search ellipse. By default, uses the whole point array.

--radius2 <val>

The second radius (Y axis if rotation angle is 0) of the search ellipse. By default, uses the whole point array.

--angle <val>

Angle of search ellipse rotation in degrees (counter clockwise, default is 0).

--max-points <val>

Maximum number of data points to use. Do not search for more points than this number. This may only used if the search ellipse is set (both radii are non-zero). By default, no limitation.

--min-points <val>

Minimum number of data points to use. If less points in the search ellipse than the specified value are found, the grid node considered empty and will be filled with the nodata value. This may only used if the search ellipse is set (both radii are non-zero). By default, no limitation.

--max-points-per-quadrant <val>

Maximum number of data points to use per quadrant. By default, no limitation. When specified, the algorithm will only take into account up to max_points_per_quadrant points for each of the right-top, left-top, right-bottom and right-top quadrant relative to the point being interpolated.

--min-points-per-quadrant <val>

Minimum number of data points to use per quadrant. By default, no limitation. When specified, the algorithm will collect at least min_points_per_quadrant points for each of the right-top, left-top, right-bottom and right-top quadrant relative to the point being interpolated.

--nodata <val>

Nodata value to fill empty points (default is 0).

"invdistnn" algorithm

Interpolation using an inverse distance to a power with nearest neighbor searching, ideal when *--max-points* is used.

When *--min-points-per-quadrant* or *--max-points-per-quadrant* is specified, the search will start with the closest point to the point being interpolated from the first quadrant, then the closest point to the point being interpolated from the second quadrant, etc. up to the 4th quadrant, and will continue with the next closest point in the first quadrant, etc. until *--max-points* and/or *--max-points-per-quadrant* thresholds are reached.

Required option

--radius <val>

Set search radius (mutually exclusive with *--radius1* and *--radius2*. Required.

Options

--power <val>

Weighting power (default 2.0).

--smoothing <val>

Smoothing parameter (default 0.0).

--max-points <val>

Maximum number of data points to use. Do not search for more points than this number. This may only used if the search ellipse is set (both radii are non-zero). By default, no limitation.

--min-points <val>

Minimum number of data points to use. If less points in the search ellipse than the specified value are found, the grid node considered empty and will be filled with the nodata value. This may only used if the search ellipse is set (both radii are non-zero). By default, no limitation.

--max-points-per-quadrant <val>

Maximum number of data points to use per quadrant. By default, no limitation. When specified, the algorithm will only take into account up to max_points_per_quadrant points for each of the right-top, left-top, right-bottom and right-top quadrant relative to the point being interpolated.

--min-points-per-quadrant <val>

Minimum number of data points to use per quadrant. By default, no limitation. When specified, the algorithm will collect at least min_points_per_quadrant points for each of the right-top, left-top, right-bottom and right-top quadrant relative to the point being interpolated.

--nodata <val>

Nodata value to fill empty points (default is 0).

"average" algorithm

Interpolation using a moving average algorithm.

When *--min-points-per-quadrant* or *--max-points-per-quadrant* is specified, the search will start with the closest point to the point being interpolated from the first quadrant, then the closest point to the point being interpolated from the second quadrant, etc. up to the 4th quadrant, and will continue with the next closest point in the first quadrant, etc. until *--max-points* and/or *--max-points-per-quadrant* thresholds are reached.

Options

--radius <val>

Set first and second radius (mutually exclusive with *--radius1* and *--radius2*. By default, uses the whole point array.

--radius1 <val>

The first radius (X axis if rotation angle is 0) of the search ellipse. By default, uses the whole point array.

--radius2 <val>

The second radius (Y axis if rotation angle is 0) of the search ellipse. By default, uses the whole point array.

--angle <val>

Angle of search ellipse rotation in degrees (counter clockwise, default is 0).

--max-points <val>

Maximum number of data points to use. Do not search for more points than this number. This may only used if the search ellipse is set (both radii are non-zero). By default, no limitation.

--min-points <val>

Minimum number of data points to use. If less points in the search ellipse than the specified value are found, the grid node considered empty and will be filled with the nodata value. This may only used if the search ellipse is set (both radii are non-zero). By default, no limitation.

--max-points-per-quadrant <val>

Maximum number of data points to use per quadrant. By default, no limitation. When specified, the algorithm will only take into account up to max_points_per_quadrant points for each of the right-top, left-top, right-bottom and right-top quadrant relative to the point being interpolated.

--min-points-per-quadrant <val>

Minimum number of data points to use per quadrant. By default, no limitation. When specified, the algorithm will collect at least min_points_per_quadrant points for each of the right-top, left-top, right-bottom and right-top quadrant relative to the point being interpolated.

--nodata <val>

Nodata value to fill empty points (default is 0).

"nearest" algorithm

Interpolation using nearest neighbor algorithm.

Options

--radius <val>

Set first and second radius (mutually exclusive with *--radius1* and *--radius2*. By default, uses the whole point array.

--radius1 <val>

The first radius (X axis if rotation angle is 0) of the search ellipse. By default, uses the whole point array.

--radius2 <val>

The second radius (Y axis if rotation angle is 0) of the search ellipse. By default, uses the whole point array.

--angle <val>

Angle of search ellipse rotation in degrees (counter clockwise, default is 0).

--nodata <val>

Nodata value to fill empty points (default is 0).

"linear" algorithm

Linear interpolation by computing a Delaunay triangulation of the point cloud, finding in which triangle of the triangulation the point is, and by doing linear interpolation from its barycentric coordinates within the triangle. If the point is not in any triangle, depending on the radius, the algorithm will use the value of the nearest point or the nodata value.

Options

--radius <val>

In case the point to be interpolated does not fit into a triangle of the Delaunay triangulation, use that maximum distance to search a nearest neighbour, or use nodata otherwise. If unset, the search distance is infinite. If set to 0, nodata value will be always used.

--nodata <val>

Nodata value to fill empty points (default is 0).

Data metrics algorithms

Besides the interpolation functionality **gdal vector grid** can be used to compute some data metrics using the specified window and output grid geometry. These metrics are:

- `minimum`: Minimum value found in grid node search ellipse.
- `maximum`: Maximum value found in grid node search ellipse.
- `range`: A difference between the minimum and maximum values found in grid node search ellipse.
- `count`: A number of data points found in grid node search ellipse.
- `average-distance`: An average distance between the grid node (center of the search ellipse) and all of the data points found in grid node search ellipse.
- `average-distance-points`: An average distance between the data points found in grid node search ellipse. The distance between each pair of points within ellipse is calculated and average of all distances is set as a grid node value.

All the metrics have the same set of options:

--radius <val>

Set first and second radius (mutually exclusive with *--radius1* and *--radius2*. By default, uses the whole point array.

--radius1 <val>

The first radius (X axis if rotation angle is 0) of the search ellipse. By default, uses the whole point array.

--radius2 <val>

The second radius (Y axis if rotation angle is 0) of the search ellipse. By default, uses the whole point array.

--angle <val>

Angle of search ellipse rotation in degrees (counter clockwise, default is 0).

--min-points <val>

Minimum number of data points to use. If less points in the search ellipse than the specified value are found, the grid node considered empty and will be filled with the nodata value. This may only used if the search ellipse is set (both radii are non-zero). By default, no limitation.

--max-points-per-quadrant <val>

Maximum number of data points to use per quadrant. By default, no limitation. When specified, the algorithm will only take into account up to max_points_per_quadrant points for each of the right-top, left-top, right-bottom and right-top quadrant relative to the point being interpolated.

--min-points-per-quadrant <val>

Minimum number of data points to use per quadrant. By default, no limitation. If that number is not reached, the point being interpolated will be set with the nodata value. When specified, the algorithm will collect at least min_points_per_quadrant points for each of the right-top, left-top, right-bottom and right-top quadrant relative to the point being interpolated.

--nodata <val>

Nodata value to fill empty points (default is 0).

When *--min-points-per-quadrant* or *--max-points-per-quadrant* is specified, the search will start with the closest point to the point being interpolated from the first quadrant, then the closest point to the point being interpolated from the second quadrant, etc. up to the 4th quadrant, and will continue with the next closest point in the first quadrant, etc. until *--max-points* and/or *--max-points-per-quadrant* thresholds are reached.

Reading comma separated values

Often you have a text file with a list of comma separated XYZ values to work with (so called CSV file). You can easily use that kind of data source in **gdal vector grid**. All you need is to create a virtual dataset header (VRT) for your CSV file and use it as an input datasource for **gdal vector grid**. You can find details on the VRT format on the *VRT -- OGR Virtual Format* description page.

Here is a small example. Let's say we have a CSV file called *dem.csv* containing

```
Easting,Northing,Elevation
86943.4,891957,139.13
87124.3,892075,135.01
86962.4,892321,182.04
87077.6,891995,135.01
...
```

For the above data we will create a *dem.vrt* header with the following content:

```
<OGRVRTDataSource>
    <OGRVRTLayer name="dem">
        <SrcDataSource>dem.csv</SrcDataSource>
        <GeometryType>wkbPoint</GeometryType>
        <GeometryField encoding="PointFromColumns" x="Easting" y="Northing" z="Elevation
↪"/>
    </OGRVRTLayer>
</OGRVRTDataSource>
```

This description specifies so called 2.5D geometry with three coordinates X, Y and Z. The Z value will be used for interpolation. Now you can use *dem.vrt* with all OGR programs (start with *ogrinfo* to test that everything works fine). The datasource will contain a single layer called *"dem"* filled with point features constructed from values in the CSV file. Using this technique you can handle CSV files with more than three columns, switch columns, etc. OK, now the final step:

```
gdal vector grid invdist dem.vrt demv.tif
```

Or, if we do not wish to use a VRT file:

```
gdal vector grid invdist -l dem -oo X_POSSIBLE_NAMES=Easting \
-oo Y_POSSIBLE_NAMES=Northing --zfield=Elevation dem.csv dem.tif
```

If your CSV file does not contain column headers then it can be handled in the VRT file in the following way:

```
<GeometryField encoding="PointFromColumns" x="field_1" y="field_2" z="field_3"/>
```

The *Comma Separated Value (.csv)* description page contains details on CSV format supported by GDAL.

Added in version 3.12.

GDALG output (on-the-fly / streamed dataset)

This program supports serializing the command line as a JSON file using the `GDALG` output format. The resulting file can then be opened as a raster dataset using the *GDALG: GDAL Streamed Algorithm* driver, and apply the specified pipeline in a on-the-fly / streamed way.

> **Note**
>
> However this algorithm is not natively streaming compatible. Consequently a temporary dataset will be generated, which may cause significant processing time at opening.

Return status code

The program returns status code 0 in case of success, and non-zero in case of error (non-blocking errors emitted as warnings are considered as a successful execution).

Examples

Example 1: Create a raster from a VRT datasource using inverse distance to a power

```
gdal vector grid invdist --power=2.0 --smoothing=1.0 --extent=85000,894000,89000,890000 \
    --size=400,400 -l dem dem.vrt dem.tif
```

This example creates a raster TIFF file from the VRT datasource described in *Reading comma separated values* section using the inverse distance to a power method. Values to interpolate will be read from Z value of geometry record.

Example 2: Read values to interpolate from an attribute field

```
gdal vector grid invdist --zfield=Elevation --config GDAL_NUM_THREADS ALL_CPUS \
    --power=2.0 --smoothing=1.0 --extent=85000,894000,89000,890000 \
    --size=400,400 -l dem dem.vrt dem.tif
```

This command does the same thing as the previous one, but reads values to interpolate from the attribute field specified with `--zfield` option instead of geometry record. So in this case X and Y coordinates are being taken from geometry and Z is being taken from the *"Elevation"* field. The `GDAL_NUM_THREADS` is also set to parallelize the computation.

5.1.4.20 gdal vector index

Added in version 3.12.

Synopsis

```
Usage: gdal vector index [OPTIONS] <INPUT>... <OUTPUT>

Create a vector index of vector datasets.

Positional arguments:
  -i, --input <INPUT>                                    Input vector datasets [may be␣
↪repeated] [required]
  -o, --output <OUTPUT>                                  Output vector dataset [required]

Common Options:
  -h, --help                                             Display help message and exit
  --json-usage                                           Display usage as JSON document␣
↪and exit
  --config <KEY>=<VALUE>                                 Configuration option [may be␣
↪repeated]
  -q, --quiet                                            Quiet mode (no progress bar or␣
```

↪only, instead of suffixed with the layer index
```

Description

gdal vector index creates a vector dataset with a record for each input vector file, an attribute containing the filename (suffixed with comma and the index of the layer within the dataset) and a polygon geometry outlining the (rectangular) extent. This output is suitable for use with MapServer as a vector tileindex

Program-Specific Options

--absolute-path

The absolute path to the vector files is stored in the index file. By default the vector filenames will be put in the file exactly as they are specified on the command line.

--accept-different-crs

Whether layers with different CRS are accepted. By default, unless *--output-crs* is specified, layers that do not have the same CRS as the first index layer will be skipped. Setting *--accept-different-crs* may be useful to avoid the CRS consistency check.

--accept-different-schemas

Whether layers with different schemas are accepted. By default, layers that do not have the same schemas as the first index layer will be skipped.

--dataset-name-only

Whether to write the dataset name only, instead of suffixed with the layer index.

> **Warning**
>
> Setting this option will generate a location not compatible with MapServer.

--filename-filter `<FILENAME-FILTER>`

Pattern that the filenames contained in input directories should follow. '*' is a wildcard character that matches any number of any characters including none. '?' is a wildcard character that matches a single character. Comparisons are done in a case insensitive way. Several filters may be specified.

For example: `--filename-filter "*.shp,*.gpkg"`

--location-name `<LOCATION-NAME>`

The output field name to hold the file path/location to the indexed vectors. The default field name is `location`.

--metadata `<KEY>=<VALUE>`

Write an arbitrary layer metadata item, for formats that support layer metadata. This option may be repeated.

--output-crs `<OUTPUT-CRS>`

Envelopes of the input files will be transformed to the desired target coordinate reference system. Default creates simple rectangular polygons in the same coordinate reference system as the input vectors.

--recursive

Whether input directories should be explored recursively.

--source-crs-field-name `<SOURCE-CRS-FIELD-NAME>`

The name of the field to store the CRS of each tile. This field name can be used as the value of the TILESRS keyword in MapServer

--source-crs-format `auto|WKT|EPSG|PROJ`

The format in which the CRS of each tile must be written. Types can be `auto`, `WKT`, `EPSG`, `PROJ`. This option should be used together with *--source-crs-field-name*.

--source-layer-name `<SOURCE-LAYER-NAME>`

Add layer of specified name from each source file in the tile index [may be repeated] If none of

--source-layer-index `<SOURCE-LAYER-INDEX>`

Add layer of specified index (0-based) from each source file in the tile index [may be repeated]

Standard Options

--append

Whether appending features to existing layer(s) is allowed. This also creates the output dataset if it does not exist yet.

--co, --creation-option <NAME>=<VALUE>

Many formats have one or more optional dataset creation options that can be used to control particulars about the file created. For instance, the GeoPackage driver supports creation options to control the version.

May be repeated.

The dataset creation options available vary by format driver, and some simple formats have no creation options at all. A list of options supported for a format can be listed with the *--formats* command line option but the documentation for the format is the definitive source of information on driver creation options. See *Vector drivers* format specific documentation for legal creation options for each format.

Note that dataset creation options are different from layer creation options.

--lco, --layer-creation-option <NAME>=<VALUE>

Many formats have one or more optional layer creation options that can be used to control particulars about the layer created. For instance, the GeoPackage driver supports layer creation options to control the feature identifier or geometry column name, setting the identifier or description, etc.

May be repeated.

The layer creation options available vary by format driver, and some simple formats have no layer creation options at all. A list of options supported for a format can be listed with the *--formats* command line option but the documentation for the format is the definitive source of information on driver creation options. See *Vector drivers* format specific documentation for legal creation options for each format.

Note that layer creation options are different from dataset creation options.

-f, --of, --format, --output-format <OUTPUT-FORMAT>

Which output vector format to use. Allowed values may be given by `gdal --formats | grep vector | grep rw | sort`

--nln, --output-layer <LAYER>

Provides a name for the output vector layer.

--overwrite

Allow program to overwrite existing target file or dataset. Otherwise, by default, **gdal** errors out if the target file or dataset already exists.

--overwrite-layer

Whether overwriting the existing output vector layer is allowed.

--update

Whether to open an existing output dataset in update mode.

Return status code

The program returns status code 0 in case of success, and non-zero in case of error (non-blocking errors emitted as warnings are considered as a successful execution).

Examples

Example 1

Produce a GeoPackage with a record for every layer that the utility found in the `countries` folder. Each record holds information that points to the location of each input vector file and also a bounding rectangle shape showing its bounds:

```
gdal vector index countries/*.shp index.gpkg
```

Example 2

The *--output-crs* option can also be used to transform all input vector envelopes into the same output projection:

```
gdal vector index --output-crs EPSG:4326 --source-crs-field-name=src_srs countries/*.shp␣
↪index.gpkg
```

5.1.4.21 gdal vector layer-algebra

Added in version 3.12.

Synopsis

```
Usage: gdal vector layer-algebra [OPTIONS] <OPERATION> <INPUT> <METHOD> <OUTPUT>

Perform algebraic operation between 2 layers.

Positional arguments:

```

Description

gdal vector layer-algebra performs various vector layer algebraic operations. The command takes a vector input source and a method source and generates the output of the operation in the specified output file.

Program-Specific Options

--geometry-type <GEOMETRY-TYPE>

Change the geometry type to be one of `GEOMETRY`, `POINT`, `LINESTRING`, `POLYGON`, `MULTIPOINT`, `MULTILINESTRING`, `MULTIPOLYGON`, `GEOMETRYCOLLECTION`, `CURVE`, `CIRCULARSTRING`, `COMPOUNDCURVE`, `SURFACE`, `CURVEPOLYGON`, `MULTICURVE`, `MULTISURFACE`, `POLYHEDRALSURFACE` or `TIN`. `Z`, `M` or `ZM` suffixes can be appended to the above values to indicate the dimensionality.

--input-layer <INPUT-LAYER>

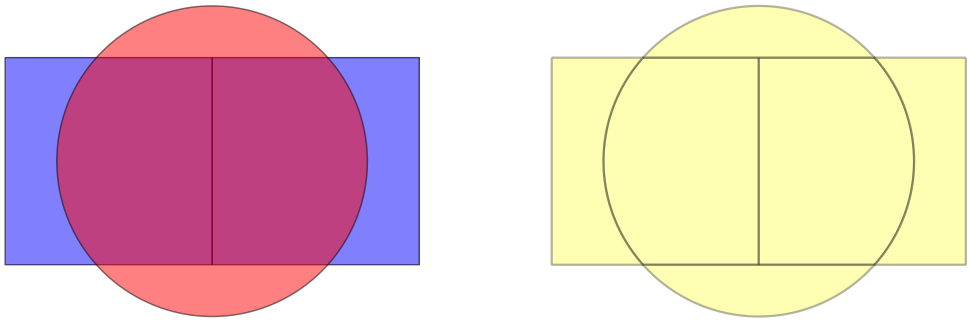
Name of the input vector layer.

--operation `union|intersection|sym-difference|identity|update|clip|erase`

Select the operation to perform among:

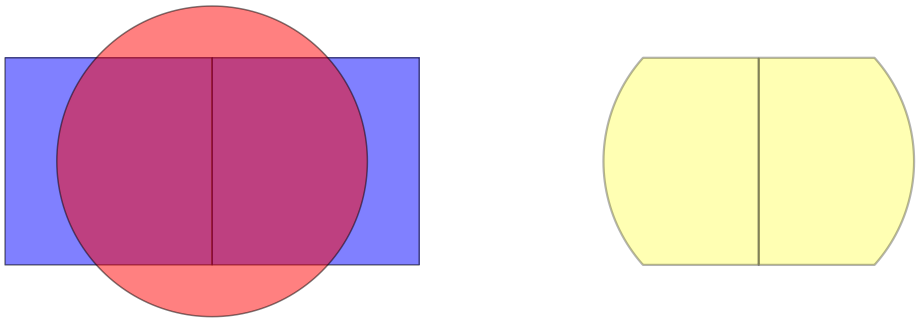
- `union`

  A union is a set of features, which represent areas that are in either of the operand layers. The operation is symmetric, and input and method layers can be interchanged.



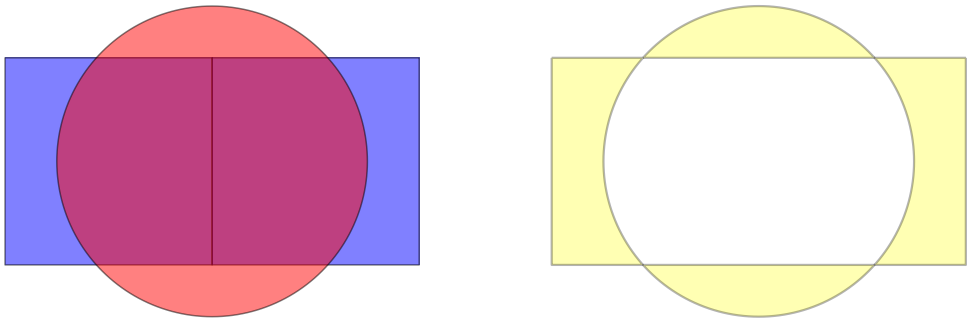
- `intersection`

  An intersection is a set of features, which represent the common areas of two layers. The operation is symmetric, and input and method layers can be interchanged.



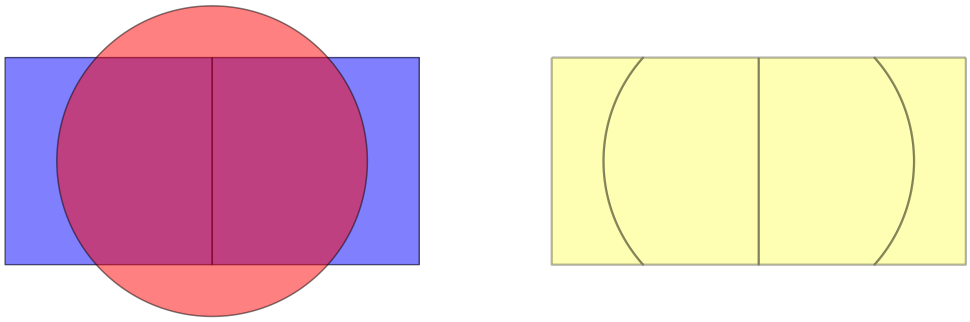
- `sym-difference`

  A symmetric difference is a set of features, which represent areas that are in operand layers but which do not intersect. The operation is symmetric, and input and method layers can be interchanged.



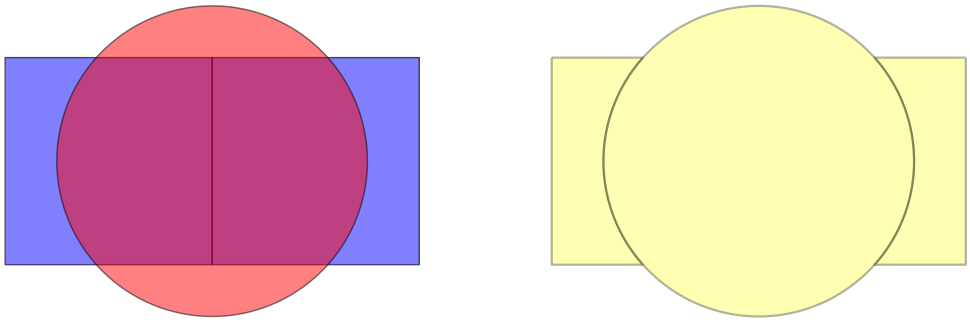
- `identity`

  The identity method identifies features in the input layer with features in the method layer possibly splitting features into several features. By default the result layer has attributes from both operand layers.



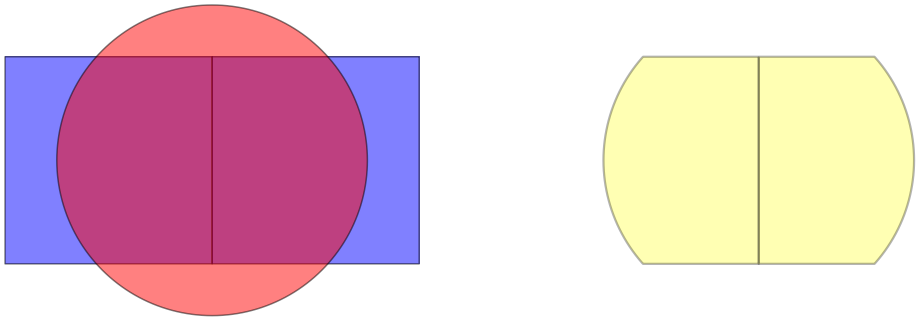
- `update`

  The update method creates a layer, which add features into the input layer from the method layer possibly cutting features in the input layer. By default the result layer has attributes only from the input layer.



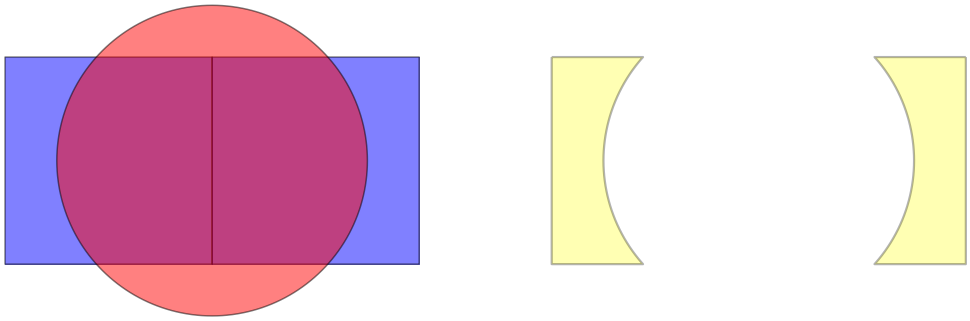
- `clip`

  The clip method creates a layer, which has features from the input layer clipped to the areas of the features in the method layer. By default the result layer has attributes of the input layer.



- `erase`

  The erase method creates a layer, which has features from the input layer whose areas are erased by the features in the method layer. By default the result layer has attributes of the input layer.



--method-layer <METHOD-LAYER>

Name of the method vector layer.

Advanced options

--all-input-field

Add all input fields to output layer. Mutually exclusive with *--input-field*, *--no-input-field*.

--all-method-field

Add all method fields to output layer. Mutually exclusive with *--method-field*, *--no-method-field*.

--input-field <INPUT-FIELD>

Input field(s) to add to output layer [may be repeated] Mutually exclusive with *--no-input-field*, *--all-input-field*.

--input-prefix <INPUT-PREFIX>

Prefix for fields corresponding to input layer. Defaults to `input_` if there are both input and method fields, otherwise empty string.

--method-field <METHOD-FIELD>

Input field(s) to add to output layer [may be repeated] Mutually exclusive with *--no-method-field*, *--all-method-field*.

--method-prefix <METHOD-PREFIX>

Prefix for fields corresponding to method layer. Defaults to `method_` if there are both input and method fields, otherwise empty string.

--no-input-field

Do not add any input field to output layer. Mutually exclusive with *--input-field*, *--all-input-field*.

--no-method-field

Do not add any method field to output layer. Mutually exclusive with *--method-field*, *--all-method-field*.

Standard Options

--append

Whether appending features to existing layer(s) is allowed. This also creates the output dataset if it does not exist yet.

--co, --creation-option <NAME>=<VALUE>

Many formats have one or more optional dataset creation options that can be used to control particulars about the file created. For instance, the GeoPackage driver supports creation options to control the version.

May be repeated.

The dataset creation options available vary by format driver, and some simple formats have no creation options at all. A list of options supported for a format can be listed with the *--formats* command line option but the documentation for the format is the definitive source of information on driver creation options. See *Vector drivers* format specific documentation for legal creation options for each format.

Note that dataset creation options are different from layer creation options.

--if, --input-format <format>

Format/driver name to be attempted to open the input file(s). It is generally not necessary to specify it, but it can be used to skip automatic driver detection, when it fails to select the appropriate driver. This option can be repeated several times to specify several candidate drivers. Note that it does not force those drivers to open the dataset. In particular, some drivers have requirements on file extensions.

May be repeated.

--lco, --layer-creation-option <NAME>=<VALUE>

Many formats have one or more optional layer creation options that can be used to control particulars about the layer created. For instance, the GeoPackage driver supports layer creation options to control the feature identifier or geometry column name, setting the identifier or description, etc.

May be repeated.

The layer creation options available vary by format driver, and some simple formats have no layer creation options at all. A list of options supported for a format can be listed with the *--formats* command line option but the documentation for the format is the definitive source of information on driver creation options. See *Vector drivers* format specific documentation for legal creation options for each format.

Note that layer creation options are different from dataset creation options.

--oo, --open-option <NAME>=<VALUE>

Dataset open option (format specific).

May be repeated.

-f, --of, --format, --output-format <OUTPUT-FORMAT>

Which output vector format to use. Allowed values may be given by `gdal --formats | grep vector | grep rw | sort`

--output-layer <NAME>

Specifies the name of the layer to which features will be written. If not specified, output layer names will be the same as input layer names.

--overwrite

Allow program to overwrite existing target file or dataset. Otherwise, by default, **gdal** errors out if the target file or dataset already exists.

--overwrite-layer

Whether overwriting the existing output vector layer is allowed.

--update

Whether to open an existing output dataset in update mode.

Return status code

The program returns status code 0 in case of success, and non-zero in case of error (non-blocking errors emitted as warnings are considered as a successful execution).

Examples

Example 1: Performs a union between both input and method layers.

```
$ gdal vector layer-algebra union input.shp method.shp output.shp
```

5.1.4.22 gdal vector make-point

Added in version 3.12.

Synopsis

```
Usage: gdal vector make-point [OPTIONS] <INPUT> <OUTPUT>

Create point geometries from attribute fields

```

Description

gdal vector make-point creates point geometries from attribute fields containing coordinates.

Program-Specific Options

--output-crs <CRS>

Optional coordinate reference system to assign to the created points. The coordinate reference systems that can be passed are anything supported by the *OGRSpatialReference::SetFromUserInput()* call, which includes EPSG Projected, Geographic or Compound CRS (i.e. EPSG:4296), a well known text (WKT) CRS definition, PROJ.4 declarations, or the name of a .prj file containing a WKT CRS definition.

--m <FIELD_NAME>

Optional field name containing M coordinate values

--x <FIELD_NAME>

Field name containing X coordinate values

--y <FIELD_NAME>

Field name containing Y coordinate values

--z <FIELD_NAME>

Optional field name containing Z coordinate values

Standard Options

--append

Whether appending features to existing layer(s) is allowed. This also creates the output dataset if it does not exist yet.

--co, --creation-option <NAME>=<VALUE>

Many formats have one or more optional dataset creation options that can be used to control particulars about the file created. For instance, the GeoPackage driver supports creation options to control the version.

May be repeated.

The dataset creation options available vary by format driver, and some simple formats have no creation options at all. A list of options supported for a format can be listed with the *--formats* command line option but the documentation for the format is the definitive source of information on driver creation options. See *Vector drivers* format specific documentation for legal creation options for each format.

Note that dataset creation options are different from layer creation options.

--if, --input-format <format>

Format/driver name to be attempted to open the input file(s). It is generally not necessary to specify it, but it can be used to skip automatic driver detection, when it fails to select the appropriate driver. This option can be repeated several times to specify several candidate drivers. Note that it does not force those drivers to open the dataset. In particular, some drivers have requirements on file extensions.

May be repeated.

--input-layer <INPUT-LAYER>

Specifies the name of one or more layers to process. By default, all layers will be processed.

--lco, --layer-creation-option <NAME>=<VALUE>

Many formats have one or more optional layer creation options that can be used to control particulars about the layer created. For instance, the GeoPackage driver supports layer creation options to control the feature identifier or geometry column name, setting the identifier or description, etc.

May be repeated.

The layer creation options available vary by format driver, and some simple formats have no layer creation options at all. A list of options supported for a format can be listed with the *--formats* command line option but the documentation for the format is the definitive source of information on driver creation options. See *Vector drivers* format specific documentation for legal creation options for each format.

Note that layer creation options are different from dataset creation options.

--oo, --open-option <NAME>=<VALUE>

Dataset open option (format specific).

May be repeated.

-f, --of, --format, --output-format <OUTPUT-FORMAT>

Which output vector format to use. Allowed values may be given by `gdal --formats | grep vector | grep rw | sort`

--output-layer <NAME>

Specifies the name of the layer to which features will be written. If not specified, output layer names will be the same as input layer names.

--output-open-option, --output-oo <NAME>=<VALUE>

Added in version 3.12.

Dataset open option for output dataset (format specific).

May be repeated.

--overwrite

Allow program to overwrite existing target file or dataset. Otherwise, by default, **gdal** errors out if the target file or dataset already exists.

--overwrite-layer

Whether overwriting the existing output vector layer is allowed.

--skip-errors

Added in version 3.12.

Whether failures to write feature(s) should be ignored. Note that this option sets the size of the transaction unit to one feature at a time, which may cause severe slowdown when inserting into databases.

--update

Whether to open an existing output dataset in update mode.

--upsert

Added in version 3.12.

Variant of *--append* where the *OGRLayer::UpsertFeature()* operation is used to insert or update features instead of appending with *OGRLayer::CreateFeature()*.

This is currently implemented only in a few drivers: *GPKG -- GeoPackage vector*, *Elasticsearch: Geographically Encoded Objects for Elasticsearch* and *MongoDBv3* (drivers that implement upsert expose the *GDAL_DCAP_UPSERT* capability).

The upsert operation uses the FID of the input feature, when it is set (and the FID column name is not the empty string), as the key to update existing features. It is crucial to make sure that the FID in the source and target layers are consistent.

For the GPKG driver, it is also possible to upsert features whose FID is unset or non-significant (the `--unset-fid` option of *gdal vector edit* can be used to ignore the FID from the source feature), when there is a UNIQUE column that is not the integer primary key.

Return status code

The program returns status code 0 in case of success, and non-zero in case of error (non-blocking errors emitted as warnings are considered as a successful execution).

5.1.4.23 gdal vector make-valid

Added in version 3.12.

Synopsis

```
Usage: gdal vector make-valid [OPTIONS] <INPUT> <OUTPUT>

Fix validity of geometries of a vector dataset.

Positional arguments:
  -i, --input <INPUT>                                    Input vector datasets [required]␣
↪[not available in pipelines]
  -o, --output <OUTPUT>                                  Output vector dataset [required]␣
↪[not available in pipelines]

Common Options:
  -h, --help                                             Display help message and exit
  --json-usage                                           Display usage as JSON document␣
↪and exit
  --config <KEY>=<VALUE>                                 Configuration option [may be␣
```

(continues on next page)

(continued from previous page)

```
↪repeated]
  -q, --quiet                                          Quiet mode (no progress bar or␣
↪warning message) [not available in pipelines]

Options:
  -l, --layer, --input-layer <INPUT-LAYER>             Input layer name(s) [may be␣
↪repeated] [not available in pipelines]
  -f, --of, --format, --output-format <OUTPUT-FORMAT>  Output format ("GDALG" allowed)␣
↪[not available in pipelines]
  --co, --creation-option <KEY>=<VALUE>                Creation option [may be repeated]␣
↪[not available in pipelines]
  --lco, --layer-creation-option <KEY>=<VALUE>         Layer creation option [may be␣
↪repeated] [not available in pipelines]
  --overwrite                                          Whether overwriting existing␣
↪output dataset is allowed [not available in pipelines]
  --update                                             Whether to open existing dataset␣
↪in update mode [not available in pipelines]
  --overwrite-layer                                    Whether overwriting existing␣
↪output layer is allowed [not available in pipelines]
  --append                                             Whether appending to existing␣
↪layer is allowed [not available in pipelines]
                                                       Mutually exclusive with --upsert
  --output-layer <OUTPUT-LAYER>                        Output layer name [not available␣
↪in pipelines]
  --skip-errors                                        Skip errors when writing features␣
↪[not available in pipelines]
  --active-layer <ACTIVE-LAYER>                        Set active layer (if not␣
↪specified, all)
  --active-geometry <ACTIVE-GEOMETRY>                  Geometry field name to which to␣
↪restrict the processing (if not specified, all)
  --method <METHOD>                                    Algorithm to use when repairing␣
↪invalid geometries.. METHOD=linework|structure (default: linework)
  --keep-lower-dim                                     Keep components of lower␣
↪dimension after MakeValid()

Advanced Options:
  --if, --input-format <INPUT-FORMAT>                  Input formats [may be repeated]␣
↪[not available in pipelines]
  --oo, --open-option <KEY>=<VALUE>                    Open options [may be repeated]␣
↪[not available in pipelines]
  --output-oo, --output-open-option <KEY>=<VALUE>      Output open options [may be␣
↪repeated] [not available in pipelines]
  --upsert                                             Upsert features (implies 'append
↪') [not available in pipelines]
                                                       Mutually exclusive with --append
```

Description

gdal vector make-valid ensures that geometries are valid regarding the rules of the Simple Features specification.

It runs the *OGRGeometry::MakeValid()* operation, followed by *OGRGeometryFactory::removeLowerDimensionSubGeoms()* (unless *--keep-lower-dim* is set)

It can also be used as a step of *gdal vector pipeline*.

> **Note**
>
> This command requires a GDAL build against the GEOS library.

GDALG output (on-the-fly / streamed dataset)

This program supports serializing the command line as a JSON file using the `GDALG` output format. The resulting file can then be opened as a vector dataset using the *GDALG: GDAL Streamed Algorithm* driver, and apply the specified pipeline in a on-the-fly / streamed way.

Program-Specific Options

--keep-lower-dim

Keep components of lower dimension after MakeValid(). For example, MakeValid() may return a GeometryCollection of a Polygon and a LineString from a Polygon input. By default only the Polygon would be returned. Setting this option will return the GeometryCollection.

--method=`linework|structure`

Algorithm to use when repairing invalid geometries.

The default `linework` method combines all rings into a set of noded lines and then extracts valid polygons from that linework. This method keeps all input vertices.

The `structure` method (only available with GEOS >= 3.10) first makes all rings valid then merges shells and subtracts holes from shells to generate valid result. It assumes that holes and shells are correctly categorized.

For examples of the differences between these methods, see *Geometry Validity*.

Standard Options

--active-geometry `<ACTIVE-GEOMETRY>`

Set the active geometry field from its name. When it is specified, only the specified geometry field will be subject to the processing. Other geometry fields will be not modified. If this option is not specified, all geometry fields will be subject to the processing. This option can be combined together with `--active-layer`.

--active-layer `<ACTIVE-LAYER>`

Set the active layer. When it is specified, only the layer specified by its name will be subject to the processing. Other layers will be not modified. If this option is not specified, all layers will be subject to the processing.

--append

Whether appending features to existing layer(s) is allowed. This also creates the output dataset if it does not exist yet.

--co, --creation-option `<NAME>=<VALUE>`

Many formats have one or more optional dataset creation options that can be used to control particulars about the file created. For instance, the GeoPackage driver supports creation options to control the version.

May be repeated.

The dataset creation options available vary by format driver, and some simple formats have no creation options at all. A list of options supported for a format can be listed with the *--formats* command line option but the documentation for the format is the definitive source of information on driver creation options. See *Vector drivers* format specific documentation for legal creation options for each format.

Note that dataset creation options are different from layer creation options.

--if, --input-format <format>

Format/driver name to be attempted to open the input file(s). It is generally not necessary to specify it, but it can be used to skip automatic driver detection, when it fails to select the appropriate driver. This option can be repeated several times to specify several candidate drivers. Note that it does not force those drivers to open the dataset. In particular, some drivers have requirements on file extensions.

May be repeated.

--input-layer <INPUT-LAYER>

Specifies the name of one or more layers to process. By default, all layers will be processed. To read and write all layers but only process a subset, use *--active-layer*.

--lco, --layer-creation-option <NAME>=<VALUE>

Many formats have one or more optional layer creation options that can be used to control particulars about the layer created. For instance, the GeoPackage driver supports layer creation options to control the feature identifier or geometry column name, setting the identifier or description, etc.

May be repeated.

The layer creation options available vary by format driver, and some simple formats have no layer creation options at all. A list of options supported for a format can be listed with the *--formats* command line option but the documentation for the format is the definitive source of information on driver creation options. See *Vector drivers* format specific documentation for legal creation options for each format.

Note that layer creation options are different from dataset creation options.

--oo, --open-option <NAME>=<VALUE>

Dataset open option (format specific).

May be repeated.

-f, --of, --format, --output-format <OUTPUT-FORMAT>

Which output vector format to use. Allowed values may be given by `gdal --formats | grep vector | grep rw | sort`

--output-layer <NAME>

Specifies the name of the layer to which features will be written. If not specified, output layer names will be the same as input layer names.

--output-open-option, --output-oo <NAME>=<VALUE>

Added in version 3.12.

Dataset open option for output dataset (format specific).

May be repeated.

--overwrite

Allow program to overwrite existing target file or dataset. Otherwise, by default, **gdal** errors out if the target file or dataset already exists.

--overwrite-layer

Whether overwriting the existing output vector layer is allowed.

--skip-errors

Added in version 3.12.

Whether failures to write feature(s) should be ignored. Note that this option sets the size of the transaction unit to one feature at a time, which may cause severe slowdown when inserting into databases.

--update

Whether to open an existing output dataset in update mode.

--upsert

Added in version 3.12.

Variant of *--append* where the *OGRLayer::UpsertFeature()* operation is used to insert or update features instead of appending with *OGRLayer::CreateFeature()*.

This is currently implemented only in a few drivers: *GPKG -- GeoPackage vector*, *Elasticsearch: Geographically Encoded Objects for Elasticsearch* and *MongoDBv3* (drivers that implement upsert expose the *GDAL_DCAP_UPSERT* capability).

The upsert operation uses the FID of the input feature, when it is set (and the FID column name is not the empty string), as the key to update existing features. It is crucial to make sure that the FID in the source and target layers are consistent.

For the GPKG driver, it is also possible to upsert features whose FID is unset or non-significant (the `--unset-fid` option of *gdal vector edit* can be used to ignore the FID from the source feature), when there is a UNIQUE column that is not the integer primary key.

Return status code

The program returns status code 0 in case of success, and non-zero in case of error (non-blocking errors emitted as warnings are considered as a successful execution).

Examples

Example 1: Basic use of make-valid

```
$ gdal vector make-valid in.gpkg out.gpkg --overwrite
```

5.1.4.24 gdal vector materialize

Added in version 3.12.

Description

The `materialize` operation is for use only in a pipeline, and writes the incoming dataset to a dataset on disk, before passing that materialized dataset to following steps. This can be used when materializing a dataset helps for performance compared to on-demand evaluation of previous steps.

By default, a GeoPackage file (or a Spatialite file if GeoPackage cannot support some features of the input dataset) is used for the materialized dataset, created in the directory pointed by the *CPL_TMPDIR* configuration option or in the current directory if not specified, and is deleted when the pipeline finishes. The user can also select another format, or specify an explicit filename, in which case the materialized dataset is not deleted when the pipeline finishes.

Synopsis

```
* materialize [OPTIONS]
------------------------

Materialize a piped dataset on disk to increase the efficiency of the following steps.

Options:
```

(continues on next page)

(continued from previous page)

```
  -o, --output <OUTPUT>                                  Materialized dataset name␣
↪(created by algorithm)
  -f, --of, --format, --output-format <OUTPUT-FORMAT>  Output format
  --co, --creation-option <KEY>=<VALUE>                  Creation option [may be repeated]
  --lco, --layer-creation-option <KEY>=<VALUE>           Layer creation option [may be␣
↪repeated]
  --overwrite                                            Whether overwriting existing␣
↪output dataset is allowed
```

Program-Specific Options

--output <OUTPUT>

Optional dataset name. When specified, it is not removed at the end of the process.

Standard Options

--co, --creation-option <NAME>=<VALUE>

Many formats have one or more optional dataset creation options that can be used to control particulars about the file created. For instance, the GeoPackage driver supports creation options to control the version.

May be repeated.

The dataset creation options available vary by format driver, and some simple formats have no creation options at all. A list of options supported for a format can be listed with the *--formats* command line option but the documentation for the format is the definitive source of information on driver creation options. See *Vector drivers* format specific documentation for legal creation options for each format.

Note that dataset creation options are different from layer creation options.

--lco, --layer-creation-option <NAME>=<VALUE>

Many formats have one or more optional layer creation options that can be used to control particulars about the layer created. For instance, the GeoPackage driver supports layer creation options to control the feature identifier or geometry column name, setting the identifier or description, etc.

May be repeated.

The layer creation options available vary by format driver, and some simple formats have no layer creation options at all. A list of options supported for a format can be listed with the *--formats* command line option but the documentation for the format is the definitive source of information on driver creation options. See *Vector drivers* format specific documentation for legal creation options for each format.

Note that layer creation options are different from dataset creation options.

--overwrite

Allow program to overwrite existing target file or dataset. Otherwise, by default, **gdal** errors out if the target file or dataset already exists.

Return status code

The program returns status code 0 in case of success, and non-zero in case of error (non-blocking errors emitted as warnings are considered as a successful execution).

Examples

Example 1: Reproject a GeoPackage file to CRS EPSG:32632 ("WGS 84 / UTM zone 32N"), materialize it to a temporary file and rasterize it

```
$ gdal pipeline ! read in.gpkg ! reproject --output-crs=EPSG:32632 ! \
                ! materialize ! rasterize --resolution 10,10 ! write out.gpkg --overwrite
```

5.1.4.25 gdal vector partition

Added in version 3.12.

Synopsis

```
Usage: gdal vector partition [OPTIONS] <INPUT> <OUTPUT>

Partition a vector dataset into multiple files.

Positional arguments:
  -i, --input <INPUT>                                    Input vector datasets [required]␣

↪[not available in pipelines]
```

Description

gdal vector partition dispatches features into different files, depending on the values the feature take on a subset of attribute or geometry fields specified by the user and/or by limiting each output layer to a maximum number of features and/or a maximum file size.

Two partitioning schemes are available:

- `hive`, corresponding to Apache Hive partitioning, is the default one.

  Each partitioning field corresponds to a nested directory. Let's consider a layer with fields "continent" and "country", chosen as partitioning fields. All features where "continent" evaluates to "Europe" and "country" evaluates to "France", will be written in the "continent=Europe/country=France/" subdirectory of the output directory.

  NULL values for partitioning fields are encoded as `__HIVE_DEFAULT_PARTITION__` in the directory name. Non-ASCII characters, space, equal sign, or characters not compatible with directory name constraints are percent-encoded (e.g. `%20` for space).

- `flat` where files are written directly under the output directory using a default filename pattern of `{LAYER_NAME}_{FIELD_VALUE}_%10d`.

By default, the format of the input dataset will be used for the output, if it can be determined and the input driver supports writing. Otherwise, *--format* must be used.

gdal vector partition can be used as the last step of a pipeline.

The following options are available:

Program-Specific Options

--feature-limit <FEATURE-LIMIT>

Maximum number of features per file. By default, unlimited. If the limit is exceeded, several parts are created.

--field <FIELD-NAME>

Fields(s) on which to partition

Only attribute fields of type String, Integer and Integer64 are allowed. The order into which fields are specified matter to determine the directory hierarchy.

Starting with GDAL 3.13, geometry field names can be specified (`OGR_GEOMETRY` being the generic name for the first geometry field). Partitioning on geometry fields is done on the geometry type. This can be useful for file formats where a single geometry type per layer is allowed.

Starting with GDAL 3.13, *--field* is no longer required, but when it is not specified, *--feature-limit* and/or *--max-file-size* must be specified.

--max-file-size <MAX-FILE-SIZE>

Maximum file size (MB or GB suffix can be used). By default, unlimited. If the limit is exceeded, several parts are created.

Note that the maximum file size is used as a hint, and might not be strictly respected, because the evaluation of the file size corresponding to a feature is based on a heuristics, as the file size itself cannot be reliably used when it is under writing. In particular, the heuristics does not assume any compression, so for compressed formats, the actual size of a part can be significantly smaller than the specified limit.

--omit-partitioned-field

Whether to omit partitioned fields from the target layer definition. Automatically set for Parquet output format and Hive partitioning.

--output <OUTPUT-DIRECTORY>

Root of the output directory. [required]

--pattern <PATTERN>

Filename pattern. User chosen string, with substitutions for:

- `{LAYER_NAME}`, when found, is substituted with the layer name (percent encoded where needed).
- `{FIELD_VALUE}`, when found, is substituted with the partitioning field value (percent encoded where needed). If several partitioning fields are used, each value is separated by underscore (_). Empty strings are substituted with `__EMPTY__` and null fields with `__NULL__`.
- `%[0?][0-9]?[0]?d`: C-style integer formatter for the part number. Valid values are for example `%d` or `%05d`. One and only one part number specifier must be present in the pattern.

Default values for the pattern are `part_%010d` for the hive scheme, and `{LAYER_NAME}_{FIELD_VALUE}_%010d` for the flat scheme.`

--scheme `hive|flat`

Partitioning scheme. Defaults to `hive`.

Standard Options

--append

Whether the output directory must be opened in append mode. Implies that it already exists and that the output format supports appending.

This mode is useful when adding new features to an already an existing partitioned dataset.

--co, --creation-option <NAME>=<VALUE>

Many formats have one or more optional dataset creation options that can be used to control particulars about the file created. For instance, the GeoPackage driver supports creation options to control the version.

May be repeated.

The dataset creation options available vary by format driver, and some simple formats have no creation options at all. A list of options supported for a format can be listed with the *--formats* command line option but the documentation for the format is the definitive source of information on driver creation options. See *Vector drivers* format specific documentation for legal creation options for each format.

Note that dataset creation options are different from layer creation options.

--if, --input-format <format>

Format/driver name to be attempted to open the input file(s). It is generally not necessary to specify it, but it can be used to skip automatic driver detection, when it fails to select the appropriate driver. This option can be repeated several times to specify several candidate drivers. Note that it does not force those drivers to open the dataset. In particular, some drivers have requirements on file extensions.

May be repeated.

--lco, --layer-creation-option <NAME>=<VALUE>

Many formats have one or more optional layer creation options that can be used to control particulars about the layer created. For instance, the GeoPackage driver supports layer creation options to control the feature identifier or geometry column name, setting the identifier or description, etc.

May be repeated.

The layer creation options available vary by format driver, and some simple formats have no layer creation options at all. A list of options supported for a format can be listed with the *--formats* command line option but the documentation for the format is the definitive source of information on driver creation options. See *Vector drivers* format specific documentation for legal creation options for each format.

Note that layer creation options are different from dataset creation options.

--oo, --open-option <NAME>=<VALUE>

Dataset open option (format specific).

May be repeated.

-f, --of, --format, --output-format <OUTPUT-FORMAT>

Which output vector format to use. Allowed values may be given by `gdal --formats | grep vector | grep rw | sort`

--overwrite

Allow program to overwrite existing target file or dataset. Otherwise, by default, **gdal** errors out if the target file or dataset already exists.

--skip-errors

Added in version 3.12.

Whether failures to write feature(s) should be ignored. Note that this option sets the size of the transaction unit to one feature at a time, which may cause severe slowdown when inserting into databases.

Return status code

The program returns status code 0 in case of success, and non-zero in case of error (non-blocking errors emitted as warnings are considered as a successful execution).

Examples

Example 1: Create a partition based on the "continent" and "country" fields

```
$ gdal vector partition world_cities.gpkg out_directory --field continent,country --
↪format Parquet
```

Example 2: Create a partition based on the "country" field, filtering on cities with population bigger than 1 million, with a flat partitioning scheme

```
$ gdal pipeline ! read world_cities.gpkg ! filter --where "pop > 1e6" ! partition out_
↪directory --field country --format GPKG --scheme flat
```

Example 3: Create multiple Shapefiles, one for each geometry type, from a GeoPackage file, by grouping together POLYGON/MULTIPOLYGON or LINESTRING/MULTILINESTRING.

```
$ gdal vector pipeline ! read input.gpkg ! set-geom-type --multi ! partition out_
↪directory --scheme flat --field OGR_GEOMETRY --format "ESRI Shapefile"
```

Example 4: Split a file into files with at most 100,000 features.

```
$ gdal vector partition world_cities.gpkg out_directory --feature-limit 100000 --scheme␣
↪flat --format Parquet
```

Example 5: Sort a file spatially and split it into files with at most 100,000 features.

```
$ gdal vector pipeline read world_cities.gpkg ! sort ! partition out_directory --feature-
↪limit 100000 --scheme flat --format Parquet
```

5.1.4.26 gdal vector pipeline

Added in version 3.11.

Description

gdal vector pipeline can be used to process a vector dataset and perform various processing steps that accept vector and generate vector.

For pipelines mixing raster and vector, consult *gdal pipeline*.

Most steps proceed in on-demand evaluation of features, unless otherwise stated in their documentation, without "materializing" the resulting dataset of the operation of each step. It may be desirable sometimes for performance purposes to proceed to materializing an intermediate dataset to disk using *gdal vector materialize*.

Synopsis

```
Usage: gdal vector pipeline [OPTIONS] <PIPELINE>

Process a vector dataset applying several steps.

Positional arguments:

Common Options:
  -h, --help              Display help message and exit
  --json-usage            Display usage as JSON document and exit
  --config <KEY>=<VALUE>  Configuration option [may be repeated]
  -q, --quiet             Quiet mode (no progress bar or warning message) [not available␣
↪in pipelines]

Options:
  --skip-errors           Skip errors when writing features [not available in pipelines]

<PIPELINE> is of the form: read|concat [READ-OPTIONS] ( ! <STEP-NAME> [STEP-OPTIONS] )* !
↪ write|info [WRITE-OPTIONS]
```

A pipeline chains several steps, separated with the *!* (exclamation mark) character. The first step must be `read` or `concat`, and the last one `export-schema`, `info`, `partition` or `write`. Each step has its own positional or non-positional arguments. Apart from `read`, `concat`, `info`, `partition` and `write`, all other steps can potentially be used several times in a pipeline.

Steps

- *buffer*
- *check-coverage*
- *check-geometry*
- *clean-coverage*
- *clip*
- *combine*
- *concave-hull*
- *concat*
- *convex-hull*
- *create*
- *dissolve*
- *edit*
- *explode-collections*
- *export-schema*
- *external*
- *filter*
- *info*
- *limit*
- *make-point*
- *make-valid*
- *materialize*
- *partition*
- *read*
- *rename-layer*
- *reproject*
- *segmentize*
- *select*
- *set-field-type*
- *set-geom-type*
- *simplify*

- *simplify-coverage*
- *sort*
- *sql*
- *swap-xy*
- *tee*
- *update*
- *write*

buffer

```
* buffer [OPTIONS] <DISTANCE>
----------------------------

Compute a buffer around geometries of a vector dataset.

Positional arguments:
  --distance <DISTANCE>                    Distance to which to extend the geometry.␣
↪[required]

Options:
  --active-layer <ACTIVE-LAYER>            Set active layer (if not specified, all)
  --active-geometry <ACTIVE-GEOMETRY>      Geometry field name to which to restrict the␣
↪processing (if not specified, all)
  --endcap-style <ENDCAP-STYLE>            Endcap style.. ENDCAP-STYLE=round|flat|square␣
↪(default: round)
  --join-style <JOIN-STYLE>                Join style.. JOIN-STYLE=round|mitre|bevel␣
↪(default: round)
  --mitre-limit <MITRE-LIMIT>              Mitre ratio limit (only affects mitered join␣
↪style). (default: 5)
  --quadrant-segments <QUADRANT-SEGMENTS>  Number of line segments used to approximate a␣
↪quarter circle. (default: 8)
  --side <SIDE>                            Sets whether the computed buffer should be␣
↪single-sided or not.. SIDE=both|left|right (default: both)
```

Details for options can be found in *gdal vector buffer*.

check-coverage

```
* check-coverage [OPTIONS]
--------------------------

Check a polygon coverage for validity

Options:
  --include-valid                          Include valid inputs in output, with empty␣
↪geometry
  --geometry-field <GEOMETRY-FIELD>        Name of geometry field to check
  --maximum-gap-width <MAXIMUM-GAP-WIDTH>  Maximum width of a gap to be flagged
```

Details for options can be found in *gdal vector check-coverage*.

check-geometry

```
* check-geometry [OPTIONS]
--------------------------

Check a dataset for invalid geometries

Options:
  --include-field <INCLUDE-FIELD>    Fields from input layer to include in output␣
↪(special values: ALL and NONE) (default: NONE) [may be repeated]
  --include-valid                    Include valid inputs in output, with empty geometry
  --geometry-field <GEOMETRY-FIELD>  Name of geometry field to check
```

Details for options can be found in *gdal vector check-geometry*.

clean-coverage

```
* clean-coverage [OPTIONS]
--------------------------

Alter polygon boundaries to make shared edges identical, removing gaps and overlaps

Options:
  --active-layer <ACTIVE-LAYER>            Set active layer (if not specified, all)
  --snapping-distance <SNAPPING-DISTANCE>  Distance tolerance for snapping nodes
  --merge-strategy <MERGE-STRATEGY>        Algorithm to assign overlaps to neighboring␣
↪polygons. MERGE-STRATEGY=longest-border|max-area|min-area|min-index
  --maximum-gap-width <MAXIMUM-GAP-WIDTH>  Maximum width of a gap to be closed
```

Details for options can be found in *gdal vector clean-coverage*.

clip

```
* clip [OPTIONS]
----------------

Clip a vector dataset.

Options:
  --active-layer <ACTIVE-LAYER>    Set active layer (if not specified, all)
  --bbox <BBOX>                    Clipping bounding box as xmin,ymin,xmax,ymax
                                   Mutually exclusive with --geometry, --like
  --bbox-crs <BBOX-CRS>            CRS of clipping bounding box
  --geometry <GEOMETRY>            Clipping geometry (WKT or GeoJSON)
                                   Mutually exclusive with --bbox, --like
  --geometry-crs <GEOMETRY-CRS>    CRS of clipping geometry
  --like <DATASET>                 Dataset to use as a template for bounds
                                   Mutually exclusive with --bbox, --geometry
  --like-sql <SELECT-STATEMENT>    SELECT statement to run on the 'like' dataset
                                   Mutually exclusive with --like-where
```

(continues on next page)

(continued from previous page)

```
  --like-layer <LAYER-NAME>        Name of the layer of the 'like' dataset
  --like-where <WHERE-EXPRESSION>  WHERE SQL clause to run on the 'like' dataset
                                   Mutually exclusive with --like-sql
```

Details for options can be found in *gdal vector clip*.

combine

```
* combine [OPTIONS]
-------------------

Combine features into collections

Options:
  --group-by <GROUP-BY>                  Names of field(s) by which inputs should be␣
↪grouped [may be repeated]
  --keep-nested                          Avoid combining the components of multipart␣
↪geometries
  --add-extra-fields <ADD-EXTRA-FIELDS>  Whether to add extra fields, depending on if␣
↪they have identical values within each group. ADD-EXTRA-FIELDS=no|sometimes-
↪identical|always-identical (default: no)
```

Details for options can be found in *gdal vector combine*.

concave-hull

```
* concave-hull [OPTIONS]
------------------------

Compute the concave hull of geometries of a vector dataset.

Options:
  --active-layer <ACTIVE-LAYER>        Set active layer (if not specified, all)
  --active-geometry <ACTIVE-GEOMETRY>  Geometry field name to which to restrict the␣
↪processing (if not specified, all)
  --ratio <RATIO>                      Ratio controlling the concavity [required]
  --allow-holes                        Allow holes in the output polygon
  --tight                              Whether the hull must follow the outer boundaries␣
↪of the input polygons
```

Details for options can be found in *gdal vector concave-hull*.

concat

```
* concat [OPTIONS] <INPUTS>...
------------------------------

Concatenate vector datasets.

Positional arguments:
  -i, --input <INPUTS>                                        Input vector datasets [1..␣
```

(continues on next page)

(continued from previous page)

```
↪values] [required]

Options:
  -l, --layer, --input-layer <INPUT-LAYER>                  Input layer name(s) [may be␣
↪repeated]
  --mode <MODE>                                             Determine the strategy to␣
↪create output layers from source layers . MODE=merge-per-layer-name|stack|single␣
↪(default: merge-per-layer-name)
  --output-layer <OUTPUT-LAYER>                             Name of the output vector␣
↪layer (single mode), or template to name the output vector layers (stack mode)
  --source-layer-field-name <SOURCE-LAYER-FIELD-NAME>       Name of the new field to␣
↪add to contain identification of the source layer, with value determined from 'source-
↪layer-field-content'
  --source-layer-field-content <SOURCE-LAYER-FIELD-CONTENT>  A string, possibly using
↪{AUTO_NAME}, {DS_NAME}, {DS_BASENAME}, {DS_INDEX}, {LAYER_NAME}, {LAYER_INDEX}
  --field-strategy <FIELD-STRATEGY>                         How to determine target␣
↪fields from source fields. FIELD-STRATEGY=union|intersection (default: union)
  -s, --input-crs <INPUT-CRS>                               Input CRS
  -d, --output-crs <OUTPUT-CRS>                             Output CRS

Advanced Options:
  --if, --input-format <INPUT-FORMAT>                       Input formats [may be␣
↪repeated]
  --oo, --open-option <KEY>=<VALUE>                         Open options [may be␣
↪repeated]
```

Details for options can be found in *gdal vector concat*.

convex-hull

```
* convex-hull [OPTIONS]
-----------------------

Compute the convex hull of geometries of a vector dataset.

Options:
  --active-layer <ACTIVE-LAYER>        Set active layer (if not specified, all)
  --active-geometry <ACTIVE-GEOMETRY>  Geometry field name to which to restrict the␣
↪processing (if not specified, all)
```

Details for options can be found in *gdal vector convex-hull*.

create

```
* create [OPTIONS] <OUTPUT>
---------------------------

Create a vector dataset.

Positional arguments:
  -o, --output <OUTPUT>                                Output vector dataset [required]
```

(continues on next page)

(continued from previous page)

```
Options:
  -i, --like, --input <TEMPLATE-DATASET>                Input vector datasets
                                                        Mutually exclusive with --schema,␣
↪--field
  -l, --layer, --input-layer <INPUT-LAYER>              Input layer name(s) [may be␣
↪repeated]
  -f, --of, --format, --output-format <OUTPUT-FORMAT>  Output format ("GDALG" allowed)
  --co, --creation-option <KEY>=<VALUE>                 Creation option [may be repeated]
  --lco, --layer-creation-option <KEY>=<VALUE>          Layer creation option [may be␣
↪repeated]
  --overwrite                                           Whether overwriting existing␣
↪output dataset is allowed
  --update                                              Whether to open existing dataset␣
↪in update mode
  --overwrite-layer                                     Whether overwriting existing␣
↪output layer is allowed
  --output-layer <OUTPUT-LAYER>                         Output layer name
  --geometry-type <GEOMETRY-TYPE>                       Layer geometry type
  --geometry-field <GEOMETRY-FIELD>                     Name of the geometry field to␣
↪create (if supported by the output format) (default: geom)
  --crs <CRS>                                           Set CRS
  --fid <FID>                                           FID column name
  --schema <SCHEMA_JSON>                                Read OGR_SCHEMA and populate␣
↪field definitions from it
                                                        Mutually exclusive with --input, -
↪-field
  --field <NAME>:<TYPE>[(,<WIDTH>[,<PRECISION>])]>      Add a field definition to the␣
↪output layer [may be repeated]
                                                        Mutually exclusive with --input, -
↪-schema

Advanced Options:
  --if, --input-format <INPUT-FORMAT>                   Input formats [may be repeated]
  --oo, --open-option <KEY>=<VALUE>                     Open options [may be repeated]
  --output-oo, --output-open-option <KEY>=<VALUE>       Output open options [may be␣
↪repeated]
```

Details for options can be found in *gdal vector create*.

dissolve

```
* dissolve [OPTIONS]
--------------------

Dissolves multipart features

Options:
  --active-layer <ACTIVE-LAYER>        Set active layer (if not specified, all)
  --active-geometry <ACTIVE-GEOMETRY>  Geometry field name to which to restrict the␣
↪processing (if not specified, all)
```

Details for options can be found in *gdal vector dissolve*.

edit

```
* edit [OPTIONS]
----------------

Edit metadata of a vector dataset.

Options:
  --active-layer <ACTIVE-LAYER>    Set active layer (if not specified, all)
  --output-layer <OUTPUT-LAYER>    Output layer name
  --geometry-type <GEOMETRY-TYPE>  Layer geometry type
  --crs <CRS>                      Override CRS (without reprojection)
  --metadata <KEY>=<VALUE>         Add/update dataset metadata item [may be repeated]
  --unset-metadata <KEY>           Remove dataset metadata item [may be repeated]
  --layer-metadata <KEY>=<VALUE>   Add/update layer metadata item [may be repeated]
  --unset-layer-metadata <KEY>     Remove layer metadata item [may be repeated]
  --unset-fid                      Unset the identifier of each feature and the FID␣
↪column name
```

Details for options can be found in *gdal vector edit*.

explode-collections

```
* explode-collections [OPTIONS]
-------------------------------

Explode geometries of type collection of a vector dataset.

Options:
  --active-layer <ACTIVE-LAYER>        Set active layer (if not specified, all)
  --active-geometry <ACTIVE-GEOMETRY>  Geometry field name to which to restrict the␣
↪processing (if not specified, all)
  --geometry-type <GEOMETRY-TYPE>      Geometry type
  --skip-on-type-mismatch              Skip feature when change of feature geometry type␣
↪failed
```

Details for options can be found in *gdal vector explode-collections*.

export-schema

Added in version 3.12.

```
* export-schema [OPTIONS]
-------------------------

Export the OGR_SCHEMA from a vector dataset.

Positional arguments:

Options:
  -l, --layer, --input-layer <INPUT-LAYER>  Input layer name [may be repeated]
```

(continues on next page)

(continued from previous page)

```
  -o, --output <OUTPUT>                     Output file name. If not specified, output␣
↪is sent to stdout
  --overwrite                               Whether overwriting existing output file is␣
↪allowed
```

Details for options can be found in *gdal vector export-schema*.

external

```
* external [OPTIONS] <COMMAND>
------------------------------

Execute an external program as a step of a pipeline

Positional arguments:
  --command <COMMAND>                                  External command, optionally with
↪<INPUT> and/or <OUTPUT> or <INPUT-OUTPUT> placeholders [required]

Options:
  -f, --of, --format, --output-format <OUTPUT-FORMAT>  Output format

Advanced Options:
  --if, --input-format <INPUT-FORMAT>                  Input formats
```

Details for options can be found in *gdal external*.

filter

```
* filter [OPTIONS]
------------------

Filter a vector dataset.

Options:
  --active-layer <ACTIVE-LAYER>  Set active layer (if not specified, all)
  --bbox <BBOX>                  Bounding box as xmin,ymin,xmax,ymax
  --where <WHERE>|@<filename>    Attribute query in a restricted form of the queries␣
↪used in the SQL WHERE statement
  --update-extent                Update layer extent to take into account the filter
```

Details for options can be found in *gdal vector filter*.

info

Added in version 3.12.

```
* info [OPTIONS]
----------------

Return information on a vector dataset.

Positional arguments:
```

(continues on next page)

(continued from previous page)

```
Options:
  -f, --of, --format, --output-format <OUTPUT-FORMAT>  Output format. OUTPUT-
↪FORMAT=json|text
  -l, --layer, --input-layer <INPUT-LAYER>             Input layer name [may be repeated]
                                                       Mutually exclusive with --sql, --
↪fid
  --features                                           List all features (beware of RAM␣
↪consumption on large layers)
                                                       Mutually exclusive with --summary
  --summary                                            List the layer names and the␣
↪geometry type
                                                       Mutually exclusive with --features
  --limit <FEATURE-COUNT>                              Limit the number of features per␣
↪layer (implies --features)
  --sql <statement>|@<filename>                        Execute the indicated SQL␣
↪statement and return the result
                                                       Mutually exclusive with --input-
↪layer, --fid
  --where <WHERE>|@<filename>                          Attribute query in a restricted␣
↪form of the queries used in the SQL WHERE statement
  --fid <FID>                                          Feature identifier
                                                       Mutually exclusive with --input-
↪layer, --sql
  --dialect <DIALECT>                                  SQL dialect

Esoteric Options:
  --crs-format <CRS-FORMAT>                            Which format to use to report CRS.
↪ CRS-FORMAT=AUTO|WKT2|PROJJSON (default: AUTO)
```

Details for options can be found in *gdal vector info*.

limit

```
* limit [OPTIONS] <LIMIT>
-------------------------

Truncate a vector dataset to no more than a specified number of features.

Positional arguments:
  --limit <LIMIT>                Limit the number of features to read per layer␣
↪[required]

Options:
  --active-layer <ACTIVE-LAYER>  Set active layer (if not specified, all)
```

make-point

```
* make-point [OPTIONS]
----------------------
```

(continues on next page)

(continued from previous page)

```
Create point geometries from attribute fields

Options:
  --x <X>                    Field from which X coordinate should be read [required]
  --y <Y>                    Field from which Y coordinate should be read [required]
  --z <Z>                    Optional field from which Z coordinate should be read
  --m <M>                    Optional field from which M coordinate should be read
  --output-crs <OUTPUT-CRS>  Output CRS
```

Details for options can be found in *gdal vector make-point*.

make-valid

```
* make-valid [OPTIONS]
----------------------

Fix validity of geometries of a vector dataset.

Options:
  --active-layer <ACTIVE-LAYER>        Set active layer (if not specified, all)
  --active-geometry <ACTIVE-GEOMETRY>  Geometry field name to which to restrict the␣
↪processing (if not specified, all)
  --method <METHOD>                    Algorithm to use when repairing invalid␣
↪geometries.. METHOD=linework|structure (default: linework)
  --keep-lower-dim                     Keep components of lower dimension after␣
↪MakeValid()
```

Details for options can be found in *gdal vector make-valid*.

materialize

```
* materialize [OPTIONS]
-----------------------

Materialize a piped dataset on disk to increase the efficiency of the following steps.

Options:
  -o, --output <OUTPUT>                                Materialized dataset name␣
↪(created by algorithm)
  -f, --of, --format, --output-format <OUTPUT-FORMAT>  Output format
  --co, --creation-option <KEY>=<VALUE>                Creation option [may be repeated]
  --lco, --layer-creation-option <KEY>=<VALUE>         Layer creation option [may be␣
↪repeated]
  --overwrite                                          Whether overwriting existing␣
↪output dataset is allowed
```

Details for options can be found in *gdal vector materialize*.

partition

Added in version 3.12.

```
* partition [OPTIONS] <OUTPUT>
------------------------------

Partition a vector dataset into multiple files.

Positional arguments:
  -o, --output <OUTPUT>                                Output directory [required]

Options:
  --overwrite                                          Whether overwriting existing␣
↪output dataset is allowed
                                                       Mutually exclusive with --append
  --append                                             Whether appending to existing␣
↪layer is allowed
                                                       Mutually exclusive with --
↪overwrite
  -f, --of, --format, --output-format <OUTPUT-FORMAT>  Output format
  --co, --creation-option <KEY>=<VALUE>                Creation option [may be repeated]
  --lco, --layer-creation-option <KEY>=<VALUE>         Layer creation option [may be␣
↪repeated]
  --field <FIELD>                                      Attribute or geometry field(s) on␣
↪which to partition [may be repeated]
  --scheme <SCHEME>                                    Partitioning scheme.␣
↪SCHEME=hive|flat (default: hive)
  --pattern <PATTERN>                                  Filename pattern ('part_%010d'␣
↪for scheme=hive, '{LAYER_NAME}_{FIELD_VALUE}_%010d' for scheme=flat)
  --feature-limit <FEATURE-LIMIT>                      Maximum number of features per␣
↪file
  --max-file-size <MAX-FILE-SIZE>                      Maximum file size (MB or GB␣
↪suffix can be used)
  --omit-partitioned-field                             Whether to omit partitioned␣
↪fields from target layer definition
  --skip-errors                                        Skip errors when writing features
```

Details for options can be found in *gdal vector partition*.

read

```
* read [OPTIONS] <INPUT>
------------------------

Read a vector dataset.

Positional arguments:
  -i, --input <INPUT>                       Input vector datasets [required]

Options:
  -l, --layer, --input-layer <INPUT-LAYER>  Input layer name(s) [may be repeated]
```

(continues on next page)

(continued from previous page)

```
Advanced Options:
  --if, --input-format <INPUT-FORMAT>       Input formats [may be repeated]
  --oo, --open-option <KEY>=<VALUE>         Open options [may be repeated]
```

Details for options can be found in *gdal vector pipeline read*.

rename-layer

```
* rename-layer [OPTIONS]
------------------------

Rename layer(s) of a vector dataset.

Options:
  -l, --input-layer <INPUT-LAYER>                  Input layer name
  --output-layer <OUTPUT-LAYER>                    Output layer name
  --ascii                                          Force names to ASCII character
  --lower-case                                     Force names to lower case (only on␣
↪ASCII characters)
  --filename-compatible                            Force names to be usable as filenames
  --reserved-characters <RESERVED-CHARACTERS>      Reserved character(s) to be removed
  --replacement-character <REPLACEMENT-CHARACTER>  Replacement character when ASCII␣
↪conversion not possible
  --max-length <MAX-LENGTH>                        Maximum length of layer names
```

Details for options can be found in *gdal vector rename-layer*.

reproject

```
* reproject [OPTIONS]
---------------------

Reproject a vector dataset.

Options:
  --active-layer <ACTIVE-LAYER>  Set active layer (if not specified, all)
  -s, --input-crs <INPUT-CRS>    Input CRS
  -d, --output-crs <OUTPUT-CRS>  Output CRS [required]
```

Details for options can be found in *gdal vector reproject*.

segmentize

```
* segmentize [OPTIONS] <MAX-LENGTH>
-----------------------------------

Segmentize geometries of a vector dataset.

Positional arguments:
  --max-length <MAX-LENGTH>            Maximum length of a segment [required]
```

(continues on next page)

(continued from previous page)

```
Options:
  --active-layer <ACTIVE-LAYER>        Set active layer (if not specified, all)
  --active-geometry <ACTIVE-GEOMETRY>  Geometry field name to which to restrict the␣
↪processing (if not specified, all)
```

Details for options can be found in *gdal vector segmentize*.

select

```
* select [OPTIONS] <FIELDS>
---------------------------

Select a subset of fields from a vector dataset.

Positional arguments:
  --fields <FIELDS>              Fields to select (or exclude if --exclude) [may be␣
↪repeated] [required]

Options:
  --active-layer <ACTIVE-LAYER>  Set active layer (if not specified, all)
  --output-layer <OUTPUT-LAYER>  Output layer name
  --exclude                      Exclude specified fields
                                 Mutually exclusive with --ignore-missing-fields
  --ignore-missing-fields        Ignore missing fields
                                 Mutually exclusive with --exclude
```

Details for options can be found in *gdal vector select*.

set-field-type

```
* set-field-type [OPTIONS]
--------------------------

Modify the type of a field of a vector dataset.

Options:
  --active-layer <ACTIVE-LAYER>                   Set active layer (if not specified,␣
↪all)
  --field-name <FIELD-NAME>                       Field name [required]
                                                  Mutually exclusive with --input-field-
↪type
  --input-field-type <INPUT-FIELD-TYPE>           Source field type or subtype [required]
                                                  Mutually exclusive with --field-name
  --output-field-type, --field-type <FIELD-TYPE>  Target field type or subtype [required]
```

Details for options can be found in *gdal vector set-field-type*.

set-geom-type

```
* set-geom-type [OPTIONS]
-------------------------
```

(continues on next page)

(continued from previous page)

```
Modify the geometry type of a vector dataset.

Options:
  --active-layer <ACTIVE-LAYER>        Set active layer (if not specified, all)
  --active-geometry <ACTIVE-GEOMETRY>  Geometry field name to which to restrict the␣
↪processing (if not specified, all)
  --layer-only                         Only modify the layer geometry type
                                       Mutually exclusive with --feature-only
  --feature-only                       Only modify the geometry type of features
                                       Mutually exclusive with --layer-only
  --geometry-type <GEOMETRY-TYPE>      Geometry type
  --multi                              Force geometries to MULTI geometry types
                                       Mutually exclusive with --single
  --single                             Force geometries to non-MULTI geometry types
                                       Mutually exclusive with --multi
  --linear                             Convert curve geometries to linear types
                                       Mutually exclusive with --curve
  --curve                              Convert linear geometries to curve types
                                       Mutually exclusive with --linear
  --dim <DIM>                          Force geometries to the specified dimension.␣
↪DIM=XY|XYZ|XYM|XYZM
  --skip                               Skip feature when change of feature geometry type␣
↪failed
```

Details for options can be found in *gdal vector set-geom-type*.

simplify

```
* simplify [OPTIONS] <TOLERANCE>
--------------------------------

Simplify geometries of a vector dataset.

Positional arguments:
  --tolerance <TOLERANCE>              Distance tolerance for simplification. [required]

Options:
  --active-layer <ACTIVE-LAYER>        Set active layer (if not specified, all)
  --active-geometry <ACTIVE-GEOMETRY>  Geometry field name to which to restrict the␣
↪processing (if not specified, all)
```

Details for options can be found in *gdal vector simplify*.

simplify-coverage

```
* simplify-coverage [OPTIONS] <TOLERANCE>
-----------------------------------------

Simplify shared boundaries of a polygonal vector dataset.
```

(continues on next page)

(continued from previous page)

```
Positional arguments:
  --tolerance <TOLERANCE>        Distance tolerance for simplification. [required]

Options:
  --active-layer <ACTIVE-LAYER>  Set active layer (if not specified, all)
  --preserve-boundary            Whether the exterior boundary should be preserved.
```

Details for options can be found in *gdal vector simplify-coverage*.

sort

```
* sort [OPTIONS]
----------------

Spatially order the features in a layer

Options:
  --geometry-field <GEOMETRY-FIELD>  Name of geometry field to use in sort
  --method <METHOD>                  Geometry sorting algorithm. METHOD=hilbert|strtree␣
↪(default: hilbert)
  --use-tempfile                     Write features to a temporary file to avoid reading␣
↪the entire input dataset into memory
```

Details for options can be found in *gdal vector sort*.

sql

```
* sql [OPTIONS] <statement>|@<filename>
---------------------------------------

Apply SQL statement(s) to a dataset.

Positional arguments:
  --sql <statement>|@<filename>      SQL statement(s) [may be repeated] [required]

Options:
  -l, --output-layer <OUTPUT-LAYER>  Output layer name(s) [may be repeated]
  --dialect <DIALECT>                SQL dialect (e.g. OGRSQL, SQLITE)
```

Details for options can be found in *gdal vector sql*.

swap-xy

```
* swap-xy [OPTIONS]
-------------------

Swap X and Y coordinates of geometries of a vector dataset.

Options:
  --active-layer <ACTIVE-LAYER>        Set active layer (if not specified, all)
  --active-geometry <ACTIVE-GEOMETRY>  Geometry field name to which to restrict the␣
↪processing (if not specified, all)
```

Details for options can be found in *gdal vector swap-xy*.

tee

```
* tee [OPTIONS] [<PIPELINE>...]
------------------------------

Pipes the input into the output stream and side nested pipelines.

Positional arguments:
  --tee-pipeline <PIPELINE>  Nested pipeline [1.. values]
```

Details for options can be found in *Output nested pipeline*.

update

```
* update [OPTIONS] <OUTPUT>
---------------------------

Update an existing vector dataset with an input vector dataset.

Positional arguments:
  -o, --output <OUTPUT>                           Output vector dataset [required]

Options:
  --input-layer <INPUT-LAYER>                     Input layer name
  --output-layer <OUTPUT-LAYER>                   Output layer name
  --mode <MODE>                                   Set update mode. MODE=merge|update-
↪only|append-only (default: merge)
  --key <KEY>                                     Field(s) used as a key to identify␣
↪features [may be repeated]

Advanced Options:
  --output-oo, --output-open-option <KEY>=<VALUE>  Output open options [may be repeated]
```

Details for options can be found in *gdal vector update*.

write

```
* write [OPTIONS] <OUTPUT>
--------------------------

Write a vector dataset.

Positional arguments:
  -o, --output <OUTPUT>                                Output vector dataset [required]

Options:
  -f, --of, --format, --output-format <OUTPUT-FORMAT>  Output format ("GDALG" allowed)
  --co, --creation-option <KEY>=<VALUE>                Creation option [may be repeated]
  --lco, --layer-creation-option <KEY>=<VALUE>         Layer creation option [may be␣
↪repeated]
```

(continues on next page)

(continued from previous page)

```
  --overwrite                                            Whether overwriting existing␣
↪output dataset is allowed
  --update                                               Whether to open existing dataset␣
↪in update mode
  --overwrite-layer                                      Whether overwriting existing␣
↪output layer is allowed
  --append                                               Whether appending to existing␣
↪layer is allowed
                                                         Mutually exclusive with --upsert
  -l, --output-layer <OUTPUT-LAYER>                      Output layer name
  --skip-errors                                          Skip errors when writing features
  --no-create-empty-layers                               Avoid creating layers to which no␣
↪features will be written

Advanced Options:
  --output-oo, --output-open-option <KEY>=<VALUE>        Output open options [may be␣
↪repeated]
  --upsert                                               Upsert features (implies 'append')
                                                         Mutually exclusive with --append
```

Details for options can be found in *gdal vector pipeline write*.

GDALG output (on-the-fly / streamed dataset)

A pipeline can be serialized as a JSON file using the `GDALG` output format. The resulting file can then be opened as a vector dataset using the *GDALG: GDAL Streamed Algorithm* driver, and apply the specified pipeline in a on-the-fly / streamed way.

The `command_line` member of the JSON file should nominally be the whole command line without the final `write` step, and is what is generated by `gdal vector pipeline ! .... ! write out.gdalg.json`.

```
{
    "type": "gdal_streamed_alg",
    "command_line": "gdal vector pipeline ! read in.gpkg ! reproject --output-
↪crs=EPSG:32632"
}
```

The final `write` step can be added but if so it must explicitly specify the `stream` output format and a non-significant output dataset name.

```
{
    "type": "gdal_streamed_alg",
    "command_line": "gdal vector pipeline ! read in.gpkg ! reproject --output-
↪crs=EPSG:32632 ! write --output-format=streamed streamed_dataset"
}
```

Substitutions

Added in version 3.12.

It is possible to use **`gdal pipeline`** to use a pipeline already serialized in a .gdal.json file, and customize its existing steps, typically changing an input filename, specifying an output filename, or adding/modifying arguments of steps.

See *Substitutions*.

Nested pipeline

Added in version 3.12.

It is possible to create "nested pipelines", i.e. pipelines inside pipelines.

A nested pipeline is delimited by square brackets (`[` and `]`) surrounded by a space character.

There are 2 kinds of nested pipelines:

- input nested pipelines: where the result dataset of the nested pipeline is used as the input dataset for an argument of the main pipeline.
- output nested pipelines: where the output of a step of the main pipeline is used as the input of the nested pipeline in a following step. Output nested pipelines can only be used with the `tee` step.

See *Nested pipeline*.

Return status code

The program returns status code 0 in case of success, and non-zero in case of error (non-blocking errors emitted as warnings are considered as a successful execution).

Examples

Example 1: Reproject a GeoPackage file to CRS EPSG:32632 ("WGS 84 / UTM zone 32N")

```
$ gdal vector pipeline ! read in.gpkg ! reproject --output-crs=EPSG:32632 ! write out.
↪gpkg --overwrite
```

Example 2: Serialize the command of a reprojection of a GeoPackage file in a GDALG file, and later read it

```
$ gdal vector pipeline ! read in.gpkg ! reproject --output-crs=EPSG:32632 ! write in_
↪epsg_32632.gdalg.json --overwrite
$ gdal vector info in_epsg_32632.gdalg.json
```

Example 3: Union 2 source shapefiles (with similar structure), reproject them to EPSG:32632, keep only cities larger than 1 million inhabitants and write to a GeoPackage

```
$ gdal vector pipeline ! concat --single --output-crs=EPSG:32632 france.shp belgium.shp !
↪ filter --where "pop > 1e6" ! write out.gpkg --overwrite
```

Example 4: Filter and reproject a GeoPackage layer to a GeoJSON file

When using *select* to restrict the output fields, ensure that it appears **after** the *filter* step in the pipeline when the filter expression references fields. If a field required by the filter is removed by `select`, it will not be available and the command will fail with: `ERROR 1: "worldcity" not recognised as an available field.`

If you want the output to contain spatial data, you must also include the geometry field in the selected fields. In this example the source dataset has no named geometry column. In such cases the special field `_ogr_geometry_` can be used to reference the geometry. If no geometry field is included, reprojection will fail with: `ERROR 1: reproject: Layer 'ne_110m_populated_places_simple' has no spatial reference system`.

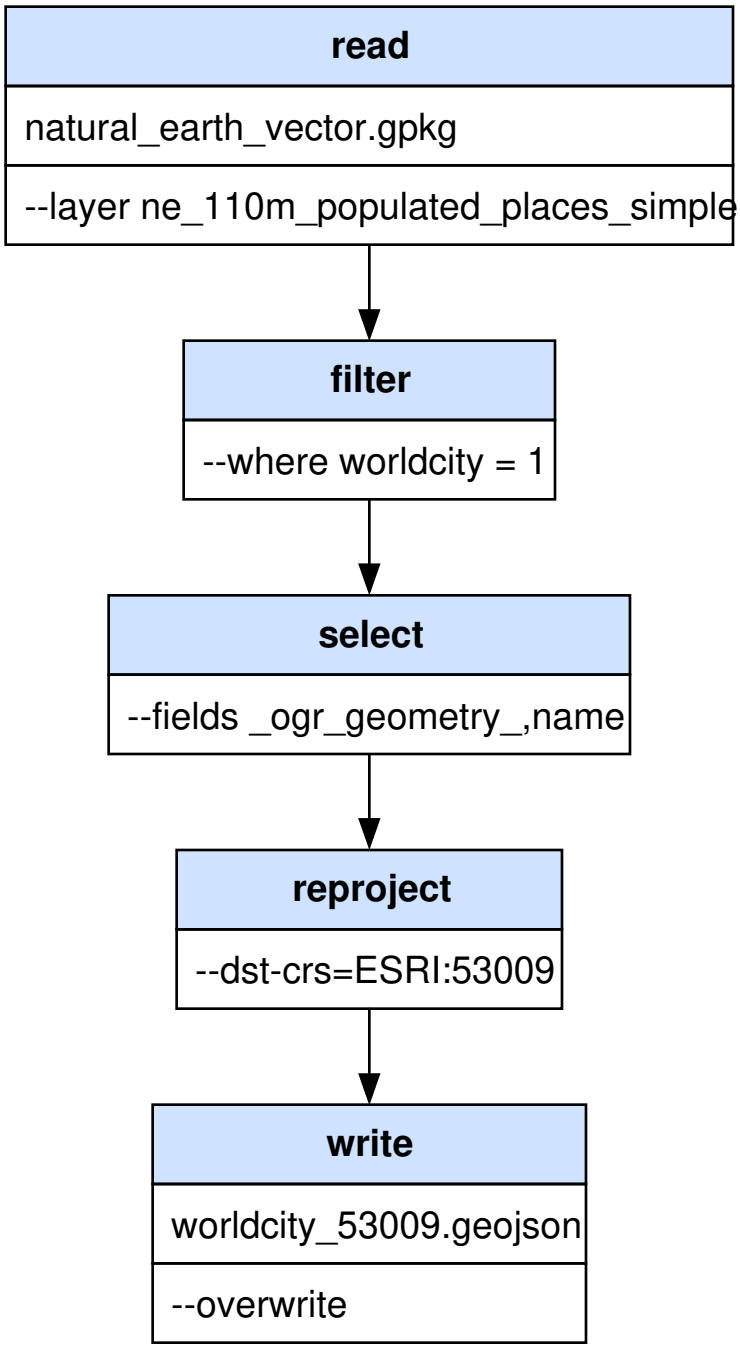
Finally, ensure that there are **no spaces** between the field names in the list. For example: `"_ogr_geometry_, name"` will produce the error: `ERROR 1: Field ' name' does not exist in layer 'ne_110m_populated_places_simple'`.

Bash

PowerShell

```
gdal vector pipeline \
    ! read natural_earth_vector.gpkg --layer ne_110m_populated_places_simple \
    ! filter --where "worldcity = 1" \
    ! select --fields "_ogr_geometry_,name" \
    ! reproject --output-crs=ESRI:53009 \
    ! write worldcity_53009.geojson --overwrite
```

```
gdal vector pipeline `
    ! read natural_earth_vector.gpkg --layer ne_110m_populated_places_simple `
    ! filter --where "worldcity = 1" `
    ! select --fields "_ogr_geometry_,name" `
    ! reproject --output-crs=ESRI:53009 `
    ! write worldcity_53009.geojson --overwrite
```



Example 5: Clip a vector layer using a nested pipeline as the clipping source

Bash

PowerShell

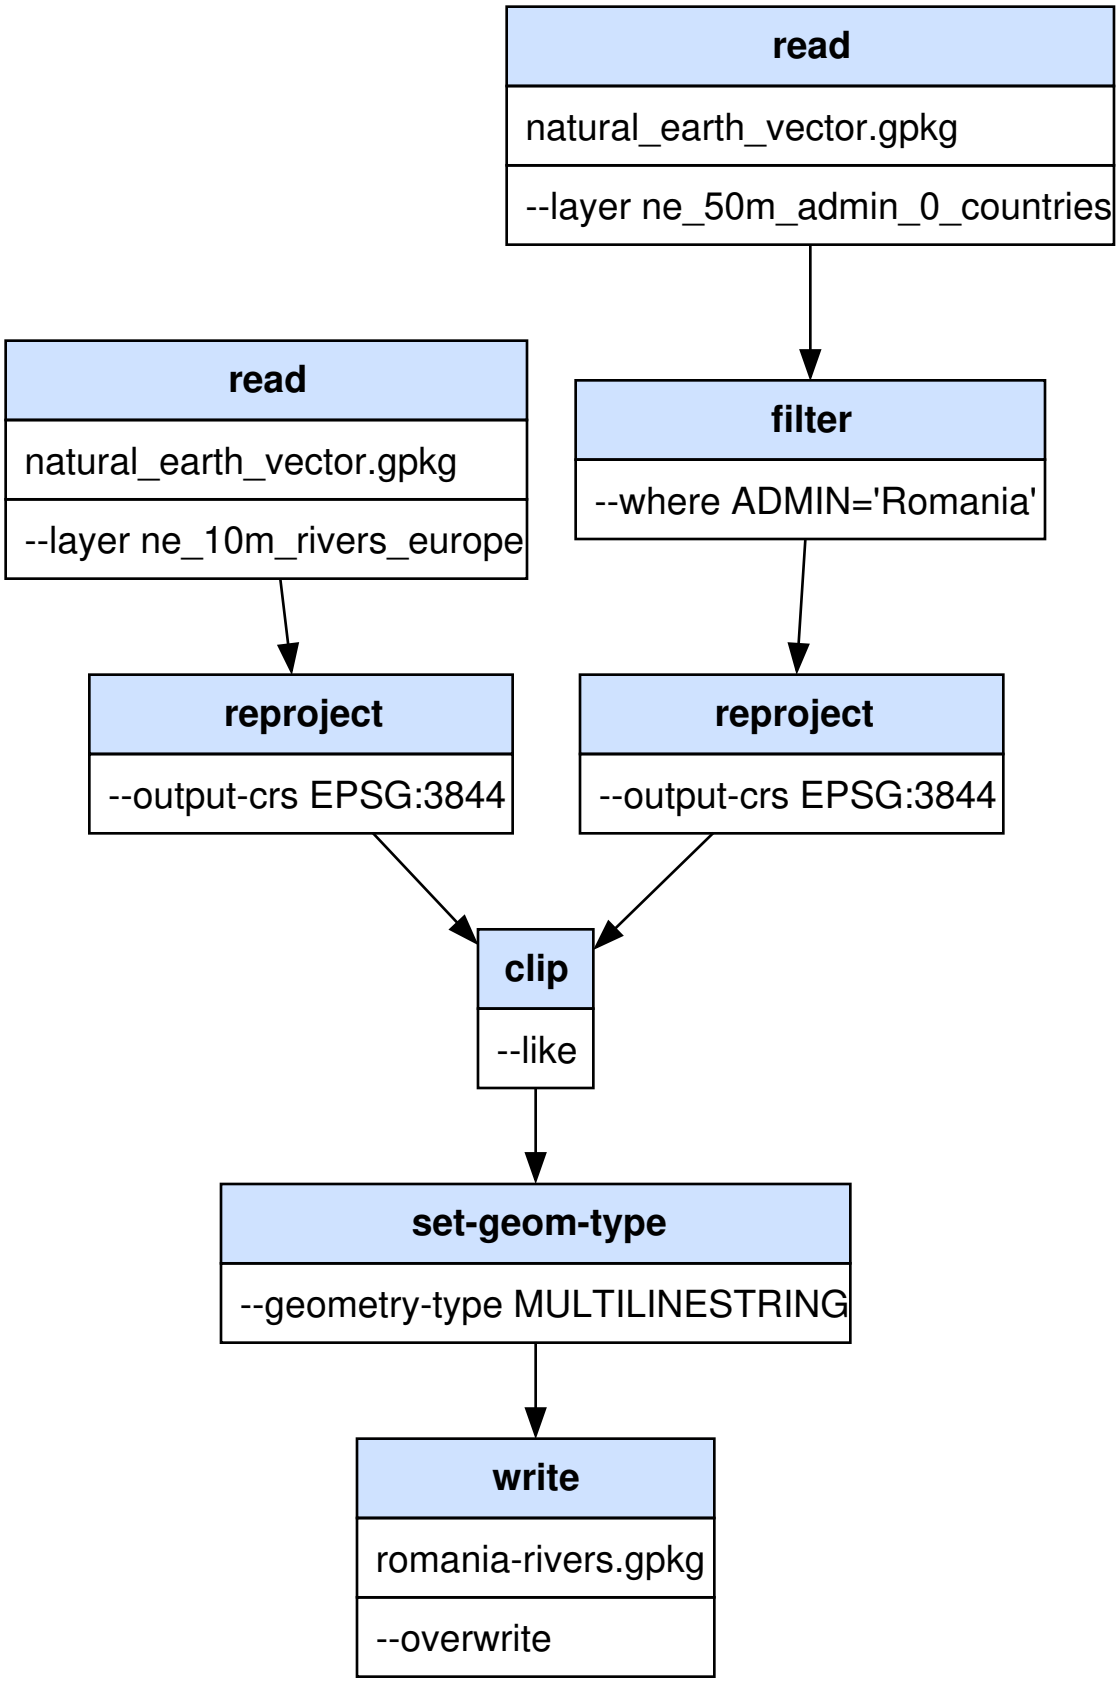
```
gdal vector pipeline \
 ! read natural_earth_vector.gpkg --layer "ne_10m_rivers_europe" \
 ! reproject --output-crs="EPSG:3844" \
 ! clip --like [ read natural_earth_vector.gpkg --layer "ne_50m_admin_0_countries" !␣
```

(continues on next page)

(continued from previous page)

```
↪filter --where "ADMIN='Romania'" ! reproject --output-crs="EPSG:3844" ] \
 ! set-geom-type --geometry-type="MULTILINESTRING" \
 ! write romania-rivers.gpkg --overwrite
```

```
gdal vector pipeline `
 ! read natural_earth_vector.gpkg --layer "ne_10m_rivers_europe" `
 ! reproject --output-crs="EPSG:3844" `
 ! clip --like [ read natural_earth_vector.gpkg --layer "ne_50m_admin_0_countries" !␣
↪filter --where "ADMIN='Romania'" ! reproject --output-crs="EPSG:3844" ] `
 ! set-geom-type --geometry-type="MULTILINESTRING" `
 ! write romania-rivers.gpkg --overwrite
```



read
natural_earth_vector.gpkg
--layer ne_50m_admin_0_countries
read
natural_earth_vector.gpkg
--layer ne_10m_rivers_europe
filter
--where ADMIN='Romania'
reproject
--output-crs EPSG:3844
reproject
--output-crs EPSG:3844
clip
--like
set-geom-type
--geometry-type MULTILINESTRING
write
romania-rivers.gpkg
--overwrite

5.1.4.27 gdal vector rasterize

Added in version 3.11.

Synopsis

```
Usage: gdal vector rasterize [OPTIONS] <INPUT> <OUTPUT>

Burns vector geometries into a raster.

Positional arguments:
  -i, --input <INPUT>                                       Input vector datasets␣
↪[required]
  -o, --output <OUTPUT>                                     Output raster dataset␣
↪[required]

Common Options:
  -h, --help                                                Display help message and exit
  --json-usage                                              Display usage as JSON␣
↪document and exit
  --config <KEY>=<VALUE>                                    Configuration option [may be␣
↪repeated]
  -q, --quiet                                               Quiet mode (no progress bar␣
↪or warning message) [not available in pipelines]

Options:
  -f, --of, --format, --output-format <OUTPUT-FORMAT>       Output format
  --co, --creation-option <KEY>=<VALUE>                     Creation option [may be␣
↪repeated]
  --overwrite                                               Whether overwriting existing␣
↪output dataset is allowed
  -b, --band <BAND>                                         The band(s) to burn values␣
↪into (1-based index) [may be repeated]
  --invert                                                  Invert the rasterization
  --all-touched                                             Enables the ALL_TOUCHED␣
↪rasterization option
  --burn <BURN>                                             Burn value [may be repeated]
  -a, --attribute-name <ATTRIBUTE-NAME>                     Attribute name

↪repeated]
```

Description

gdal vector rasterize burns vector geometries into a raster.

By default (unless `--update` or `--add`) is specified, a new raster is created with a specified resolution (`--resolution`) or size (`--size`). Pixel values will either be set to a constant (the value 1, or some other value specified with `--burn`), the Z value of feature geometries (with `--3d`), or the value of a field specified with `--attribute-name`.

The left figure illustrates the default rasterization behavior, where only pixels on the line render path are included.

The right figure shows the effect of `--all-touched`, where every pixel that touches the input polygons is included.

Since GDAL 3.12, this algorithm can be part of a *gdal pipeline*.

The following options are available:

Added in version 3.12.

GDALG output (on-the-fly / streamed dataset)

This program supports serializing the command line as a JSON file using the `GDALG` output format. The resulting file can then be opened as a raster dataset using the *GDALG: GDAL Streamed Algorithm* driver, and apply the specified pipeline in a on-the-fly / streamed way.

Note

However this algorithm is not natively streaming compatible. Consequently a temporary dataset will be generated, which may cause significant processing time at opening.

Program-Specific Options

--3d

Indicates that a burn value should be extracted from the "Z" values of the feature. Works with points and lines (linear interpolation along each segment). For polygons, works properly only if they are flat (same Z value for all vertices).

--add

Instead of burning a new value, this adds the new value to the existing raster, implies `--update`. Suitable for heatmaps for instance.

--all-touched

Enables the ALL_TOUCHED rasterization option.

> **Note**
>
> When this option is enabled, the order of the input features (lines or polygons) can affect the results. When two features touch each other, the last one (i.e. topmost) will determine the burned pixel value at the edge. You may wish to use the *--sql* option to reorder the features (ORDER BY) to achieve a more predictable result.

-a, --attribute-name <ATTRIBUTE-NAME>

Name of the attribute / field from which a burn value should be retrieved for each feature. GDAL will attempt to parse the field value as a number. If this is not successful, a value of zero will be written.

--band, -b <BAND>

The band(s) to burn values into. May be repeated.

--burn <BURN>

Burn value. May be repeated.

--crs <CRS>

Override the projection for the output file. If not specified, the projection of the input vector file will be used if available. When using this option, no reprojection of features from the CRS of the input vector to the specified CRS of the output raster, so use only this option to correct an invalid source CRS. The <CRS> may be any of the usual GDAL/OGR forms, complete WKT, PROJ.4, EPSG:n or a file containing the WKT.

--extent <xmin>,<ymin>,<xmax>,<ymax>

Set georeferenced extents. The values must be expressed in georeferenced units. If not specified, the extent of the output file will be the extent of the vector layers.

--init <INIT>

Pre-initialize output bands with specified value. May be repeated.

-l, --input-layer <INPUT-LAYER>

Indicates the layer(s) from the datasource that will be used for input features. May be specified multiple times, but at least one layer name or a -sql option must be specified (not both).

--invert

Invert rasterization. Burn the fixed burn value, or the burn value associated with the first feature into all parts of the image not inside the provided polygon.

> **Note**
>
> When the vector features contain a polygon nested within another polygon (like an island in a lake), GDAL must be built against GEOS to get correct results.

--nodata <NODATA>

Assign a specified nodata value to output bands.

--optimization <OPTIMIZATION>

Force the algorithm used (results are identical). The raster mode is used in most cases and optimise read/write operations. The vector mode is useful with a decent amount of input features and optimise the CPU use. That mode have to be used with tiled images to be efficient. The auto mode (the default) will chose the algorithm based on input and output properties.

--ot, --datatype, --output-data-type <OUTPUT-DATA-TYPE>

Force the output bands to be of the indicated data type. Defaults to `Float64`, unless the attribute field to burn is of type `Int64`, in which case `Int64` is used for the output raster data type if the output driver supports it.

--resolution <xres>,<yres>

Set target resolution. The values must be expressed in georeferenced units. Both must be positive values. Note that *--resolution* cannot be used with *--size*.

--size <xsize>,<ysize>

Set output file size in pixels and lines. Note that *--size* cannot be used with *--resolution*. If one of the two values is set to 0, it will be computed from the other value in order to preserve the aspect ratio of the extent.

--sql <SQL>|@<filename>

An SQL statement to be evaluated against the datasource to produce a virtual layer of features to be burned in. The @filename syntax can be used to indicate that the content is in the pointed filename.

--dialect <DIALECT>

SQL dialect.

By default the native SQL of an RDBMS is used when using `gdal vector sql`. If using `sql` as a step of `gdal vector pipeline`, this is only true if the step preceding `sql` is `read`, otherwise the *OGRSQL* dialect is used.

If a datasource does not support SQL natively, the default is to use the `OGRSQL` dialect, which can also be specified with any data source.

The *SQL SQLite dialect* dialect can be chosen with the `SQLITE` and `INDIRECT_SQLITE` dialect values, and this can be used with any data source. Overriding the default dialect may be beneficial because the capabilities of the SQL dialects vary.

Supported dialects can be checked with `gdal --format`. For example:

```
$ gdal --format "PostgreSQL"
[...]
Supported SQL dialects: NATIVE OGRSQL SQLITE
[...]

$ gdal --format "ESRI Shapefile"
[...]
Supported SQL dialects: OGRSQL SQLITE
[...]
```

--tap, --target-aligned-pixels

(target aligned pixels) Align the coordinates of the extent of the output file to the values of *--resolution*, such that the aligned extent includes the minimum extent. Alignment means that xmin / resx, ymin / resy, xmax / resx and ymax / resy are integer values. `--tap` requires `--resolution`.

--transformer-option <NAME>=<VALUE>

set a transformer option suitable to pass to GDALCreateGenImgProjTransformer2(). This is used when converting geometries coordinates to target raster pixel space. For example this can be used to specify RPC related transformer options.

--where <WHERE>

An optional SQL WHERE style query expression to be applied to select features to burn in from the input layer(s).

Standard Options

--co, --creation-option <NAME>=<VALUE>

Many formats have one or more optional creation options that can be used to control particulars about the file created. For instance, the GeoTIFF driver supports creation options to control compression, and whether the file should be tiled.

May be repeated.

The creation options available vary by format driver, and some simple formats have no creation options at all. A list of options supported for a format can be listed with the *--formats* command line option but the documentation for the format is the definitive source of information on driver creation options. See *Raster drivers* format specific documentation for legal creation options for each format.

--if, --input-format <format>

Format/driver name to be attempted to open the input file(s). It is generally not necessary to specify it, but it can be used to skip automatic driver detection, when it fails to select the appropriate driver. This option can be repeated several times to specify several candidate drivers. Note that it does not force those drivers to open the dataset. In particular, some drivers have requirements on file extensions.

May be repeated.

--oo, --open-option <NAME>=<VALUE>

Dataset open option (format specific).

May be repeated.

-f, --of, --format, --output-format <OUTPUT-FORMAT>

Which output raster format to use. Allowed values may be given by `gdal --formats | grep raster | grep rw | sort`

--overwrite

Allow program to overwrite existing target file or dataset. Otherwise, by default, **gdal** errors out if the target file or dataset already exists.

--update

Whether to open an existing output dataset in update mode.

Return status code

The program returns status code 0 in case of success, and non-zero in case of error (non-blocking errors emitted as warnings are considered as a successful execution).

Examples

Example 1: Burn a shapefile into a raster

The following would burn all polygons from `mask.shp` into the RGB TIFF file `work.tif` with the color red (RGB = 255,0,0).

```
gdal vector rasterize -b 1,2,3 --burn 255,0,0 -l mask mask.shp work.tif
```

Example 2: The following would burn all "class A" buildings into the output elevation file, pulling the top elevation from the ROOF_H attribute.

Burn a shapefile into a raster using a specific where condition to select features

```
gdal vector rasterize -a ROOF_H --where "class='A'" -l footprints footprints.shp city_
↪dem.tif
```

Example 3: The following would burn all polygons from footprint.shp into a new 1000x1000 rgb TIFF as the color red.

> **Note**
>
> *-b* is not used; the order of the *--burn* options determines the bands of the output raster.

```
gdal vector rasterize --burn 255,0,0 --ot Byte --size 1000,1000 -l footprints footprints.
↪shp mask.tif
```

Example 4: Burn a shapefile into a raster using a specific where condition to select features, and restrict the extent to the one of selected features

```
gdal pipeline read /vsizip/vsicurl/https://www2.census.gov/geo/tiger/TIGER2025/STATE/tl_
↪2025_us_state.zip ! \
                filter --where  "stusps = 'CA'" --update-extent ! \
                rasterize  --burn 1 --size 1500,1500 --datatype Byte ! \
                write out.png --overwrite
```

5.1.4.28 `gdal vector pipeline read`

Added in version 3.11.

Description

The `read` operation is for use in a *gdal pipeline* only, and reads a single input vector dataset. This is the first step of a pipeline.

To test simple spatial operations, the `read` step can read a single geometry in (extended) WKT format rather than a dataset.

Synopsis

```
* read [OPTIONS] <INPUT>
------------------------

Read a vector dataset.

Positional arguments:
  -i, --input <INPUT>                       Input vector datasets [required]

Options:
  -l, --layer, --input-layer <INPUT-LAYER>  Input layer name(s) [may be repeated]

Advanced Options:
  --if, --input-format <INPUT-FORMAT>       Input formats [may be repeated]
  --oo, --open-option <KEY>=<VALUE>         Open options [may be repeated]
```

Standard Options

--if, --input-format <format>

Format/driver name to be attempted to open the input file(s). It is generally not necessary to specify it, but it can be used to skip automatic driver detection, when it fails to select the appropriate driver. This option can be repeated several times to specify several candidate drivers. Note that it does not force those drivers to open the dataset. In particular, some drivers have requirements on file extensions.

May be repeated.

--oo, --open-option <NAME>=<VALUE>

Dataset open option (format specific).

May be repeated.

Examples

Example 1: Read a GeoPackage file

```
$ gdal vector pipeline read input.gpkg ! ... [other commands here] ...
```

Example 2: Read and buffer a single point

```
$ gdal vector pipeline read "SRID=32145;POINT (442922 217537)" ! buffer 20 ! ... [other␣
↪commands here] ...
```

5.1.4.29 gdal vector rename-layer

Added in version 3.13.

Synopsis

```
Usage: gdal vector rename-layer [OPTIONS] <INPUT> <OUTPUT>

Rename layer(s) of a vector dataset.
```

(continues on next page)

(continued from previous page)

```

```

Description

gdal vector rename-layer can be used to rename layer(s).

It has two modes:

- one where the user renames a single layer to a given name with *--output-layer*, combined with *--input-layer* if there are more than one layer.
- another one where the user may force various operations to alter the layer names:
  - Force characters to ASCII: *--ascii*
  - Force characters to lower case: *--lower-case*
  - Force compatibility with file names: *--filename-compatible*
  - Remove or replace characters from a list of reserved characters: *--reserved-characters*
  - Truncate to a maximum number of characters: *--max-length*

  For *--filename-compatible* and *--reserved-characters*, incompatible characters are removed, unless *--replacement-character* is specified.

  In this mode, uniqueness of layer names is also attempted by appending `_{N}` where NN is a sequence number. Uniqueness may not be achieved if *--max-length* is set to a too low value.

This subcommand is also available as a potential step of *gdal vector pipeline*

Program Specific Options

--input-layer <INPUT-LAYER>

Name of input layer. To be used together with *--output-layer*

--output-layer <OUTPUT-LAYER>

Name of output layer. If there are several input layers, *--output-layer* must also be specified.

--ascii

Force characters to ASCII. Currently only accented characters characters in Latin 1 Supplement and Latin Extended A character set have a sensible ASCII replacement. Other non-ASCII characters will be removed or replaced by the replacement character specified with *--replacement-character*

--lower-case

Force characters to lower-case. Currently only ASCII upper case characters are replaced. This option is applied after *--ascii*, if the later is specified.

--filename-compatible

Force layer names to be compatible with file names for Linux, Windows or MacOS, independently from the operating system on which this command is run.

--reserved-characters <RESERVED-CHARACTERS>

Reserved character(s) to remove or replace with the replacement character specified with *--replacement-character*

--replacement-character <REPLACEMENT-CHARACTER>

Replacement character when ASCII conversion is not possible or to substitute to reserved characters.

--max-length <MAX-LENGTH>

Truncate to a maximum number of characters

Standard Options

--append

Whether appending features to existing layer(s) is allowed. This also creates the output dataset if it does not exist yet.

--co, --creation-option <NAME>=<VALUE>

Many formats have one or more optional dataset creation options that can be used to control particulars about the file created. For instance, the GeoPackage driver supports creation options to control the version.

May be repeated.

The dataset creation options available vary by format driver, and some simple formats have no creation options at all. A list of options supported for a format can be listed with the *--formats* command line option but the documentation for the format is the definitive source of information on driver creation options. See *Vector drivers* format specific documentation for legal creation options for each format.

Note that dataset creation options are different from layer creation options.

--if, --input-format <format>

Format/driver name to be attempted to open the input file(s). It is generally not necessary to specify it, but it can be used to skip automatic driver detection, when it fails to select the appropriate driver. This option can be repeated several times to specify several candidate drivers. Note that it does not force those drivers to open the dataset. In particular, some drivers have requirements on file extensions.

May be repeated.

--lco, --layer-creation-option <NAME>=<VALUE>

Many formats have one or more optional layer creation options that can be used to control particulars about the layer created. For instance, the GeoPackage driver supports layer creation options to control the feature identifier or geometry column name, setting the identifier or description, etc.

May be repeated.

The layer creation options available vary by format driver, and some simple formats have no layer creation options at all. A list of options supported for a format can be listed with the *--formats* command line option but the documentation for the format is the definitive source of information on driver creation options. See *Vector drivers* format specific documentation for legal creation options for each format.

Note that layer creation options are different from dataset creation options.

--oo, --open-option <NAME>=<VALUE>

Dataset open option (format specific).

May be repeated.

-f, --of, --format, --output-format <OUTPUT-FORMAT>

Which output vector format to use. Allowed values may be given by `gdal --formats | grep vector | grep rw | sort`

--output-layer <NAME>

Specifies the name of the layer to which features will be written. If not specified, output layer names will be the same as input layer names.

--output-open-option, --output-oo <NAME>=<VALUE>

Added in version 3.12.

Dataset open option for output dataset (format specific).

May be repeated.

--overwrite

Allow program to overwrite existing target file or dataset. Otherwise, by default, **gdal** errors out if the target file or dataset already exists.

--overwrite-layer

Whether overwriting the existing output vector layer is allowed.

--skip-errors

Added in version 3.12.

Whether failures to write feature(s) should be ignored. Note that this option sets the size of the transaction unit to one feature at a time, which may cause severe slowdown when inserting into databases.

--update

Whether to open an existing output dataset in update mode.

--upsert

Added in version 3.12.

Variant of *--append* where the *OGRLayer::UpsertFeature()* operation is used to insert or update features instead of appending with *OGRLayer::CreateFeature()*.

This is currently implemented only in a few drivers: *GPKG -- GeoPackage vector*, *Elasticsearch: Geographically Encoded Objects for Elasticsearch* and *MongoDBv3* (drivers that implement upsert expose the *GDAL_DCAP_UPSERT* capability).

The upsert operation uses the FID of the input feature, when it is set (and the FID column name is not the empty string), as the key to update existing features. It is crucial to make sure that the FID in the source and target layers are consistent.

For the GPKG driver, it is also possible to upsert features whose FID is unset or non-significant (the `--unset-fid` option of *gdal vector edit* can be used to ignore the FID from the source feature), when there is a UNIQUE column that is not the integer primary key.

Return status code

The program returns status code 0 in case of success, and non-zero in case of error (non-blocking errors emitted as warnings are considered as a successful execution).

Examples

Example 1: Rename a given layer to a user selected name.

```
$ gdal vector rename-layer input.gpkg output.gpkg --input-layer "name with space" --
↪output-layer "without_space"
```

Example 2: Force layer names to ASCII, lower case, without space character and to be filename compatible.

```
$ gdal vector rename-layer input.gpkg output_shp_directory --output-format "ESRI␣
↪Shapefile" --ascii --lower-case --filename-compatible --reserved-characters " "
```

5.1.4.30 gdal vector reproject

Added in version 3.11.

Synopsis

```
Usage: gdal vector reproject [OPTIONS] <INPUT> <OUTPUT>

Reproject a vector dataset.

Positional arguments:
  -i, --input <INPUT>                                    Input vector datasets [required]␣
↪[not available in pipelines]
  -o, --output <OUTPUT>                                  Output vector dataset [required]␣
↪[not available in pipelines]

Common Options:
  -h, --help                                             Display help message and exit
  --json-usage                                           Display usage as JSON document␣
↪and exit
  --config <KEY>=<VALUE>                                 Configuration option [may be␣
↪repeated]
  -q, --quiet                                            Quiet mode (no progress bar or␣
↪warning message) [not available in pipelines]

Options:
  -l, --layer, --input-layer <INPUT-LAYER>               Input layer name(s) [may be␣
↪repeated] [not available in pipelines]
  -f, --of, --format, --output-format <OUTPUT-FORMAT>  Output format ("GDALG" allowed)␣
↪[not available in pipelines]
  --co, --creation-option <KEY>=<VALUE>                  Creation option [may be repeated]␣
↪[not available in pipelines]
  --lco, --layer-creation-option <KEY>=<VALUE>           Layer creation option [may be␣
↪repeated] [not available in pipelines]
  --overwrite                                            Whether overwriting existing␣
↪output dataset is allowed [not available in pipelines]
  --update                                               Whether to open existing dataset␣
↪in update mode [not available in pipelines]
  --overwrite-layer                                      Whether overwriting existing␣
↪output layer is allowed [not available in pipelines]
  --append                                               Whether appending to existing␣
↪layer is allowed [not available in pipelines]
                                                         Mutually exclusive with --upsert
  --output-layer <OUTPUT-LAYER>                          Output layer name [not available␣
↪in pipelines]
  --skip-errors                                          Skip errors when writing features␣
↪[not available in pipelines]
  --active-layer <ACTIVE-LAYER>                          Set active layer (if not␣
↪specified, all)
```

(continues on next page)

(continued from previous page)

```
  -s, --input-crs <INPUT-CRS>                          Input CRS
  -d, --output-crs <OUTPUT-CRS>                        Output CRS [required]

Advanced Options:
  --if, --input-format <INPUT-FORMAT>                  Input formats [may be repeated]␣
↪[not available in pipelines]
  --oo, --open-option <KEY>=<VALUE>                    Open options [may be repeated]␣
↪[not available in pipelines]
  --output-oo, --output-open-option <KEY>=<VALUE>      Output open options [may be␣
↪repeated] [not available in pipelines]
  --upsert                                             Upsert features (implies 'append
↪') [not available in pipelines]
                                                       Mutually exclusive with --append
```

Description

gdal vector reproject can be used to reproject a vector dataset. The program can reproject to any supported projection.

This command can also be used as a step of *gdal vector pipeline*.

GDALG output (on-the-fly / streamed dataset)

This program supports serializing the command line as a JSON file using the `GDALG` output format. The resulting file can then be opened as a vector dataset using the *GDALG: GDAL Streamed Algorithm* driver, and apply the specified pipeline in a on-the-fly / streamed way.

Program-Specific Options

--input-crs, -s, <INPUT-CRS>

Override input spatial reference. If not specified the SRS found in the input dataset will be used.

The coordinate reference systems that can be passed are anything supported by the OGRSpatialReference.SetFromUserInput() call, which includes EPSG Projected, Geographic or Compound CRS (i.e. EPSG:4296), a well known text (WKT) CRS definition, PROJ.4 declarations, or the name of a .prj file containing a WKT CRS definition.

If the SRS has an explicit vertical datum that points to a PROJ.4 geoidgrids, and the input dataset is a single band dataset, a vertical correction will be applied to the values of the dataset.

--output-crs, -d <OUTPUT-CRS>

Set output spatial reference.

The coordinate reference systems that can be passed are anything supported by the OGRSpatialReference.SetFromUserInput() call, which includes EPSG Projected, Geographic or Compound CRS (i.e. EPSG:4296), a well known text (WKT) CRS definition, PROJ.4 declarations, or the name of a .prj file containing a WKT CRS definition.

If the SRS has an explicit vertical datum that points to a PROJ.4 geoidgrids, and the input dataset is a single band dataset, a vertical correction will be applied to the values of the dataset.

Standard Options

--active-layer <ACTIVE-LAYER>

Set the active layer. When it is specified, only the layer specified by its name will be subject to the processing. Other layers will be not modified. If this option is not specified, all layers will be subject to the processing.

--append

Whether appending features to existing layer(s) is allowed. This also creates the output dataset if it does not exist yet.

--co, --creation-option <NAME>=<VALUE>

Many formats have one or more optional dataset creation options that can be used to control particulars about the file created. For instance, the GeoPackage driver supports creation options to control the version.

May be repeated.

The dataset creation options available vary by format driver, and some simple formats have no creation options at all. A list of options supported for a format can be listed with the *--formats* command line option but the documentation for the format is the definitive source of information on driver creation options. See *Vector drivers* format specific documentation for legal creation options for each format.

Note that dataset creation options are different from layer creation options.

--if, --input-format <format>

Format/driver name to be attempted to open the input file(s). It is generally not necessary to specify it, but it can be used to skip automatic driver detection, when it fails to select the appropriate driver. This option can be repeated several times to specify several candidate drivers. Note that it does not force those drivers to open the dataset. In particular, some drivers have requirements on file extensions.

May be repeated.

--input-layer <INPUT-LAYER>

Specifies the name of one or more layers to process. By default, all layers will be processed. To read and write all layers but only process a subset, use `--active-layer`.

--lco, --layer-creation-option <NAME>=<VALUE>

Many formats have one or more optional layer creation options that can be used to control particulars about the layer created. For instance, the GeoPackage driver supports layer creation options to control the feature identifier or geometry column name, setting the identifier or description, etc.

May be repeated.

The layer creation options available vary by format driver, and some simple formats have no layer creation options at all. A list of options supported for a format can be listed with the *--formats* command line option but the documentation for the format is the definitive source of information on driver creation options. See *Vector drivers* format specific documentation for legal creation options for each format.

Note that layer creation options are different from dataset creation options.

--oo, --open-option <NAME>=<VALUE>

Dataset open option (format specific).

May be repeated.

-f, --of, --format, --output-format <OUTPUT-FORMAT>

Which output vector format to use. Allowed values may be given by `gdal --formats | grep vector | grep rw | sort`

--output-layer <NAME>

Specifies the name of the layer to which features will be written. If not specified, output layer names will be the same as input layer names.

--output-open-option, --output-oo <NAME>=<VALUE>

Added in version 3.12.

Dataset open option for output dataset (format specific).

May be repeated.

--overwrite

Allow program to overwrite existing target file or dataset. Otherwise, by default, **gdal** errors out if the target file or dataset already exists.

--overwrite-layer

Whether overwriting the existing output vector layer is allowed.

--skip-errors

Added in version 3.12.

Whether failures to write feature(s) should be ignored. Note that this option sets the size of the transaction unit to one feature at a time, which may cause severe slowdown when inserting into databases.

--update

Whether to open an existing output dataset in update mode.

--upsert

Added in version 3.12.

Variant of *--append* where the *OGRLayer::UpsertFeature()* operation is used to insert or update features instead of appending with *OGRLayer::CreateFeature()*.

This is currently implemented only in a few drivers: *GPKG -- GeoPackage vector*, *Elasticsearch: Geographically Encoded Objects for Elasticsearch* and *MongoDBv3* (drivers that implement upsert expose the *GDAL_DCAP_UPSERT* capability).

The upsert operation uses the FID of the input feature, when it is set (and the FID column name is not the empty string), as the key to update existing features. It is crucial to make sure that the FID in the source and target layers are consistent.

For the GPKG driver, it is also possible to upsert features whose FID is unset or non-significant (the `--unset-fid` option of *gdal vector edit* can be used to ignore the FID from the source feature), when there is a UNIQUE column that is not the integer primary key.

-q, --quiet

Suppress progress bar and some warning messages.

Return status code

The program returns status code 0 in case of success, and non-zero in case of error (non-blocking errors emitted as warnings are considered as a successful execution).

Examples

Example 1: Reproject a GeoPackage file to CRS EPSG:32632 ("WGS 84 / UTM zone 32N")

```
$ gdal vector reproject --output-crs=EPSG:32632 in.gpkg out.gpkg --overwrite
```

Example 2: Reproject data using various CRS formats

The following examples demonstrate different ways to specify a coordinate reference system. Each command reprojects the data to the Web Mercator (EPSG:3857) projection and produces identical output.

```
# OGC CRS URI
$ gdal vector reproject \
    --output-crs="http://www.opengis.net/def/crs/EPSG/0/3857" \
    natural_earth_vector.gpkg --layer=ne_10m_populated_places \
    places.json --overwrite

# OGC CRS URN
$ gdal vector reproject \
    --output-crs="urn:ogc:def:crs:EPSG::3857" \
    natural_earth_vector.gpkg --layer=ne_10m_populated_places \
    places.json --overwrite

# PROJ string (legacy format)
$ PROJ4="+proj=merc +a=6378137 +b=6378137 +lat_ts=0 +lon_0=0 +x_0=0 +y_0=0 +k=1 +units=m␣
↪+nadgrids=@null +wktext +no_defs +type=crs"
$ gdal vector reproject \
    --output-crs="$PROJ4" \
    natural_earth_vector.gpkg --layer=ne_10m_populated_places \
    places.json --overwrite
```

Example 3: Reproject a layer in a GeoPackage to Web Mercator GeoJSON

The timezone layer cannot be fully reprojected to Web Mercator as the coordinates at the poles fall outside the extent of the Web Mercator bounding-box causing some features to be missing in the output. The following errors are returned:

```
ERROR 1: Full reprojection failed, but partial is possible if you define OGR_ENABLE_
↪PARTIAL_REPROJECTION configuration option to TRUE
ERROR 1: PROJ: webmerc: Invalid latitude
ERROR 1: Reprojection failed, err = 2049, further errors will be suppressed on the␣
↪transform object.
```

You can follow the suggestion above and enable `OGR_ENABLE_PARTIAL_REPROJECTION`. Errors from PROJ relating to invalid coordinates (`ERROR 1: PROJ: webmerc: Invalid latitude`) will still be reported, but all features will be written to the output.

```
$ gdal vector reproject \
    --output-crs=EPSG:3857 \
    --config OGR_ENABLE_PARTIAL_REPROJECTION=TRUE \
    natural_earth_vector.gpkg --layer=ne_10m_time_zones \
    ne_10m_time_zones.json \
    --overwrite
```

5.1.4.31 `gdal vector select`

Added in version 3.11.

Synopsis

```
Usage: gdal vector select [OPTIONS] <INPUT> <OUTPUT> <FIELDS>

Select a subset of fields from a vector dataset.

Positional arguments:
  -i, --input <INPUT>                                    Input vector datasets [required]␣
↪[not available in pipelines]
  -o, --output <OUTPUT>                                  Output vector dataset [required]␣
↪[not available in pipelines]
  --fields <FIELDS>                                      Fields to select (or exclude if --
↪exclude) [may be repeated] [required]

Common Options:
  -h, --help                                             Display help message and exit
  --json-usage                                           Display usage as JSON document␣
↪and exit
  --config <KEY>=<VALUE>                                 Configuration option [may be␣
↪repeated]
  -q, --quiet                                            Quiet mode (no progress bar or␣
↪warning message) [not available in pipelines]

Options:
  -l, --layer, --input-layer <INPUT-LAYER>               Input layer name(s) [may be␣
↪repeated] [not available in pipelines]
  -f, --of, --format, --output-format <OUTPUT-FORMAT>  Output format ("GDALG" allowed)␣
↪[not available in pipelines]
  --co, --creation-option <KEY>=<VALUE>                  Creation option [may be repeated]␣
↪[not available in pipelines]
  --lco, --layer-creation-option <KEY>=<VALUE>           Layer creation option [may be␣
↪repeated] [not available in pipelines]
  --overwrite                                            Whether overwriting existing␣
↪output dataset is allowed [not available in pipelines]
  --update                                               Whether to open existing dataset␣
↪in update mode [not available in pipelines]
  --overwrite-layer                                      Whether overwriting existing␣
↪output layer is allowed [not available in pipelines]
  --append                                               Whether appending to existing␣
↪layer is allowed [not available in pipelines]
                                                         Mutually exclusive with --upsert
  --output-layer <OUTPUT-LAYER>                          Output layer name
  --skip-errors                                          Skip errors when writing features␣
↪[not available in pipelines]
  --active-layer <ACTIVE-LAYER>                          Set active layer (if not␣
↪specified, all)
  --exclude                                              Exclude specified fields
                                                         Mutually exclusive with --ignore-
↪missing-fields
  --ignore-missing-fields                                Ignore missing fields
                                                         Mutually exclusive with --exclude

Advanced Options:
```

(continues on next page)

(continued from previous page)

```
  --if, --input-format <INPUT-FORMAT>                    Input formats [may be repeated]␣
↪[not available in pipelines]
  --oo, --open-option <KEY>=<VALUE>                      Open options [may be repeated]␣
↪[not available in pipelines]
  --output-oo, --output-open-option <KEY>=<VALUE>        Output open options [may be␣
↪repeated] [not available in pipelines]
  --upsert                                               Upsert features (implies 'append
↪') [not available in pipelines]
                                                         Mutually exclusive with --append
```

Description

gdal vector select can be used to select a subset of fields.

`select` can also be used as a step of *gdal vector pipeline*.

GDALG output (on-the-fly / streamed dataset)

This program supports serializing the command line as a JSON file using the `GDALG` output format. The resulting file can then be opened as a vector dataset using the *GDALG: GDAL Streamed Algorithm* driver, and apply the specified pipeline in a on-the-fly / streamed way.

Program-Specific Options

--exclude

Modifies the behavior of the algorithm such that all fields are selected, except the ones mentioned by *--fields*.

--fields <FIELDS>

Comma-separated list of fields from input layer to copy to the new layer (or to exclude if *--exclude* is specified)

Field names with spaces, commas or double-quote should be surrounded with a starting and ending double-quote character, and double-quote characters in a field name should be escaped with backslash.

Depending on the shell used, this might require further quoting. For example, to select `regular_field`, `a_field_with space, and comma` and `a field with " double quote` with a Unix shell:

```
--fields "regular_field,\"a_field_with space, and comma\",\"a field with \\\"␣
↪double quote\""
```

A field is only selected once, even if mentioned several times in the list.

Geometry fields can also be specified in the list. If the source layer has no explicit name for the geometry field, `_ogr_geometry_` must be used to select the unique geometry field.

Specifying a non-existing source field name results in an error.

--ignore-missing-fields

By default, if a field specified by *--fields* does not exist in the input layer(s), an error is emitted and the processing is stopped. When specifying *--ignore-missing-fields*, only a warning is emitted and the non existing fields are just ignored.

Standard Options

--active-layer <ACTIVE-LAYER>

Set the active layer. When it is specified, only the layer specified by its name will be subject to the processing. Other layers will be not modified. If this option is not specified, all layers will be subject to the processing.

--append

Whether appending features to existing layer(s) is allowed. This also creates the output dataset if it does not exist yet.

--co, --creation-option <NAME>=<VALUE>

Many formats have one or more optional dataset creation options that can be used to control particulars about the file created. For instance, the GeoPackage driver supports creation options to control the version.

May be repeated.

The dataset creation options available vary by format driver, and some simple formats have no creation options at all. A list of options supported for a format can be listed with the *--formats* command line option but the documentation for the format is the definitive source of information on driver creation options. See *Vector drivers* format specific documentation for legal creation options for each format.

Note that dataset creation options are different from layer creation options.

--if, --input-format <format>

Format/driver name to be attempted to open the input file(s). It is generally not necessary to specify it, but it can be used to skip automatic driver detection, when it fails to select the appropriate driver. This option can be repeated several times to specify several candidate drivers. Note that it does not force those drivers to open the dataset. In particular, some drivers have requirements on file extensions.

May be repeated.

--input-layer <INPUT-LAYER>

Specifies the name of one or more layers to process. By default, all layers will be processed. To read and write all layers but only process a subset, use `--active-layer`.

--lco, --layer-creation-option <NAME>=<VALUE>

Many formats have one or more optional layer creation options that can be used to control particulars about the layer created. For instance, the GeoPackage driver supports layer creation options to control the feature identifier or geometry column name, setting the identifier or description, etc.

May be repeated.

The layer creation options available vary by format driver, and some simple formats have no layer creation options at all. A list of options supported for a format can be listed with the *--formats* command line option but the documentation for the format is the definitive source of information on driver creation options. See *Vector drivers* format specific documentation for legal creation options for each format.

Note that layer creation options are different from dataset creation options.

--oo, --open-option <NAME>=<VALUE>

Dataset open option (format specific).

May be repeated.

-f, --of, --format, --output-format <OUTPUT-FORMAT>

Which output vector format to use. Allowed values may be given by `gdal --formats | grep vector | grep rw | sort`

--output-layer <NAME>

Specifies the name of the layer to which features will be written. If not specified, output layer names will be the same as input layer names.

--output-open-option, --output-oo <NAME>=<VALUE>

Added in version 3.12.

Dataset open option for output dataset (format specific).

May be repeated.

--overwrite

Allow program to overwrite existing target file or dataset. Otherwise, by default, **gdal** errors out if the target file or dataset already exists.

--overwrite-layer

Whether overwriting the existing output vector layer is allowed.

--skip-errors

Added in version 3.12.

Whether failures to write feature(s) should be ignored. Note that this option sets the size of the transaction unit to one feature at a time, which may cause severe slowdown when inserting into databases.

--update

Whether to open an existing output dataset in update mode.

--upsert

Added in version 3.12.

Variant of *--append* where the *OGRLayer::UpsertFeature()* operation is used to insert or update features instead of appending with *OGRLayer::CreateFeature()*.

This is currently implemented only in a few drivers: *GPKG -- GeoPackage vector*, *Elasticsearch: Geographically Encoded Objects for Elasticsearch* and *MongoDBv3* (drivers that implement upsert expose the *GDAL_DCAP_UPSERT* capability).

The upsert operation uses the FID of the input feature, when it is set (and the FID column name is not the empty string), as the key to update existing features. It is crucial to make sure that the FID in the source and target layers are consistent.

For the GPKG driver, it is also possible to upsert features whose FID is unset or non-significant (the `--unset-fid` option of *gdal vector edit* can be used to ignore the FID from the source feature), when there is a UNIQUE column that is not the integer primary key.

Return status code

The program returns status code 0 in case of success, and non-zero in case of error (non-blocking errors emitted as warnings are considered as a successful execution).

Examples

Example 1: Select the EAS_ID field and the geometry field from a Shapefile

```
$ gdal vector select in.shp out.gpkg "EAS_ID,_ogr_geometry_" --overwrite
```

Example 2: Remove sensitive fields from a layer

```
$ gdal vector select in.shp out.gpkg --exclude "name,surname,address" --overwrite
```

5.1.4.32 gdal vector segmentize

Added in version 3.12.

Synopsis

```
Usage: gdal vector segmentize [OPTIONS] <INPUT> <OUTPUT> <MAX-LENGTH>

Segmentize geometries of a vector dataset.

Positional arguments:
  -i, --input <INPUT>                                    Input vector datasets [required]␣
↪[not available in pipelines]
  -o, --output <OUTPUT>                                  Output vector dataset [required]␣
↪[not available in pipelines]
  --max-length <MAX-LENGTH>                              Maximum length of a segment␣
↪[required]

Common Options:
  -h, --help                                             Display help message and exit
  --json-usage                                           Display usage as JSON document␣
↪and exit
  --config <KEY>=<VALUE>                                 Configuration option [may be␣
↪repeated]
  -q, --quiet                                            Quiet mode (no progress bar or␣
↪warning message) [not available in pipelines]

Options:
  -l, --layer, --input-layer <INPUT-LAYER>               Input layer name(s) [may be␣
↪repeated] [not available in pipelines]
  -f, --of, --format, --output-format <OUTPUT-FORMAT>  Output format ("GDALG" allowed)␣
↪[not available in pipelines]
  --co, --creation-option <KEY>=<VALUE>                  Creation option [may be repeated]␣
↪[not available in pipelines]
  --lco, --layer-creation-option <KEY>=<VALUE>           Layer creation option [may be␣
↪repeated] [not available in pipelines]

                                                         Mutually exclusive with --append
```

Description

gdal vector segmentize ensures segments of LineStrings or rings of Polygons are not longer than the specified max length, by inserting intermediate points.

It runs the *OGRGeometry::segmentize()* operation.

It can also be used as a step of *gdal vector pipeline*.

GDALG output (on-the-fly / streamed dataset)

This program supports serializing the command line as a JSON file using the GDALG output format. The resulting file can then be opened as a vector dataset using the *GDALG: GDAL Streamed Algorithm* driver, and apply the specified pipeline in a on-the-fly / streamed way.

Program-Specific Options

--max-length <MAX-LENGTH>

The specified value of this option is the maximum distance between two consecutive points of the output geometry before intermediate points are added. The unit of the distance is georeferenced units of the source layer.

Standard Options

--active-geometry <ACTIVE-GEOMETRY>

Set the active geometry field from its name. When it is specified, only the specified geometry field will be subject to the processing. Other geometry fields will be not modified. If this option is not specified, all geometry fields will be subject to the processing. This option can be combined together with *--active-layer*.

--active-layer <ACTIVE-LAYER>

Set the active layer. When it is specified, only the layer specified by its name will be subject to the processing. Other layers will be not modified. If this option is not specified, all layers will be subject to the processing.

--append

Whether appending features to existing layer(s) is allowed. This also creates the output dataset if it does not exist yet.

--co, --creation-option <NAME>=<VALUE>

Many formats have one or more optional dataset creation options that can be used to control particulars about the file created. For instance, the GeoPackage driver supports creation options to control the version.

May be repeated.

The dataset creation options available vary by format driver, and some simple formats have no creation options at all. A list of options supported for a format can be listed with the *--formats* command line option but the documentation for the format is the definitive source of information on driver creation options. See *Vector drivers* format specific documentation for legal creation options for each format.

Note that dataset creation options are different from layer creation options.

--if, --input-format <format>

Format/driver name to be attempted to open the input file(s). It is generally not necessary to specify it, but it can be used to skip automatic driver detection, when it fails to select the appropriate driver. This option can be repeated several times to specify several candidate drivers. Note that it does not force those drivers to open the dataset. In particular, some drivers have requirements on file extensions.

May be repeated.

--input-layer <INPUT-LAYER>

Specifies the name of one or more layers to process. By default, all layers will be processed. To read and write all layers but only process a subset, use `--active-layer`.

--lco, --layer-creation-option <NAME>=<VALUE>

Many formats have one or more optional layer creation options that can be used to control particulars about the layer created. For instance, the GeoPackage driver supports layer creation options to control the feature identifier or geometry column name, setting the identifier or description, etc.

May be repeated.

The layer creation options available vary by format driver, and some simple formats have no layer creation options at all. A list of options supported for a format can be listed with the *--formats* command line option but the documentation for the format is the definitive source of information on driver creation options. See *Vector drivers* format specific documentation for legal creation options for each format.

Note that layer creation options are different from dataset creation options.

--oo, --open-option <NAME>=<VALUE>

Dataset open option (format specific).

May be repeated.

-f, --of, --format, --output-format <OUTPUT-FORMAT>

Which output vector format to use. Allowed values may be given by `gdal --formats | grep vector | grep rw | sort`

--output-layer <NAME>

Specifies the name of the layer to which features will be written. If not specified, output layer names will be the same as input layer names.

--output-open-option, --output-oo <NAME>=<VALUE>

Added in version 3.12.

Dataset open option for output dataset (format specific).

May be repeated.

--overwrite

Allow program to overwrite existing target file or dataset. Otherwise, by default, **gdal** errors out if the target file or dataset already exists.

--overwrite-layer

Whether overwriting the existing output vector layer is allowed.

--skip-errors

Added in version 3.12.

Whether failures to write feature(s) should be ignored. Note that this option sets the size of the transaction unit to one feature at a time, which may cause severe slowdown when inserting into databases.

--update

Whether to open an existing output dataset in update mode.

--upsert

Added in version 3.12.

Variant of `--append` where the *OGRLayer::UpsertFeature()* operation is used to insert or update features instead of appending with *OGRLayer::CreateFeature()*.

This is currently implemented only in a few drivers: *GPKG -- GeoPackage vector*, *Elasticsearch: Geographically Encoded Objects for Elasticsearch* and *MongoDBv3* (drivers that implement upsert expose the *GDAL_DCAP_UPSERT* capability).

The upsert operation uses the FID of the input feature, when it is set (and the FID column name is not the empty string), as the key to update existing features. It is crucial to make sure that the FID in the source and target layers are consistent.

For the GPKG driver, it is also possible to upsert features whose FID is unset or non-significant (the `--unset-fid` option of *gdal vector edit* can be used to ignore the FID from the source feature), when there is a UNIQUE column that is not the integer primary key.

Return status code

The program returns status code 0 in case of success, and non-zero in case of error (non-blocking errors emitted as warnings are considered as a successful execution).

Examples

Example 1: Make sure that segments of geometries are no longer than one km (assuming the CRS is in meters)

```
$ gdal vector segmentize --max-length=1000 in.gpkg out.gpkg --overwrite
```

5.1.4.33 gdal vector set-field-type

Added in version 3.12.

Synopsis

```
Usage: gdal vector set-field-type [OPTIONS] <INPUT> <OUTPUT>

Modify the type of a field of a vector dataset.
```

```

Description

gdal vector set-field-type can be used to modify the field type of a vector dataset:

`set-field-type` can also be used as a step of *gdal vector pipeline*.

GDALG output (on-the-fly / streamed dataset)

This program supports serializing the command line as a JSON file using the `GDALG` output format. The resulting file can then be opened as a vector dataset using the *GDALG: GDAL Streamed Algorithm* driver, and apply the specified pipeline in a on-the-fly / streamed way.

Program-Specific Options

--field-name <FIELD-NAME>

The name of the field to modify.

Mutually exclusive with *--input-field-type*. One of them is required.

--field-type, --output-field-type <FIELD-TYPE>

The new field type. Valid values are: `Integer`, `IntegerList`, `Real`, `RealList`, `String`, `StringList`, `Binary`, ` `Date`, `Time`, `DateTime`, `Integer64`, `Integer64List`. A field subtype can be specified instead of a field type. Valid values are: `Boolean`, `Int16`, `Float32`, `JSON`, `UUID`. The field type will be derived from the subtype.

--input-field-type <FIELD-TYPE>

The field type of the fields to modify. Valid values are: `Integer`, `IntegerList`, `Real`, `RealList`, `String`, `StringList`, `Binary`, ` `Date`, `Time`, `DateTime`, `Integer64`, `Integer64List`. A field subtype can be specified instead of a field type. Valid values are: `Boolean`, `Int16`, `Float32`, `JSON`, `UUID`.

Mutually exclusive with *--field-name*. One of them is required.

Standard Options

--active-layer <ACTIVE-LAYER>

Set the active layer. When it is specified, only the layer specified by its name will be subject to the processing. Other layers will be not modified. If this option is not specified, all layers will be subject to the processing.

--append

Whether appending features to existing layer(s) is allowed. This also creates the output dataset if it does not exist yet.

--co, --creation-option <NAME>=<VALUE>

Many formats have one or more optional dataset creation options that can be used to control particulars about the file created. For instance, the GeoPackage driver supports creation options to control the version.

May be repeated.

The dataset creation options available vary by format driver, and some simple formats have no creation options at all. A list of options supported for a format can be listed with the *--formats* command line option but the documentation for the format is the definitive source of information on driver creation options. See *Vector drivers* format specific documentation for legal creation options for each format.

Note that dataset creation options are different from layer creation options.

--if, --input-format <format>

Format/driver name to be attempted to open the input file(s). It is generally not necessary to specify it, but it can be used to skip automatic driver detection, when it fails to select the appropriate driver. This option can be repeated several times to specify several candidate drivers. Note that it does not force those drivers to open the dataset. In particular, some drivers have requirements on file extensions.

May be repeated.

--input-layer <INPUT-LAYER>

Specifies the name of one or more layers to process. By default, all layers will be processed. To read and write all layers but only process a subset, use `--active-layer`.

--lco, --layer-creation-option <NAME>=<VALUE>

Many formats have one or more optional layer creation options that can be used to control particulars about the layer created. For instance, the GeoPackage driver supports layer creation options to control the feature identifier or geometry column name, setting the identifier or description, etc.

May be repeated.

The layer creation options available vary by format driver, and some simple formats have no layer creation options at all. A list of options supported for a format can be listed with the *--formats* command line option but the documentation for the format is the definitive source of information on driver creation options. See *Vector drivers* format specific documentation for legal creation options for each format.

Note that layer creation options are different from dataset creation options.

--oo, --open-option <NAME>=<VALUE>

Dataset open option (format specific).

May be repeated.

-f, --of, --format, --output-format <OUTPUT-FORMAT>

Which output vector format to use. Allowed values may be given by `gdal --formats | grep vector | grep rw | sort`

--output-layer <NAME>

Specifies the name of the layer to which features will be written. If not specified, output layer names will be the same as input layer names.

--output-open-option, --output-oo <NAME>=<VALUE>

Added in version 3.12.

Dataset open option for output dataset (format specific).

May be repeated.

--overwrite

Allow program to overwrite existing target file or dataset. Otherwise, by default, **gdal** errors out if the target file or dataset already exists.

--overwrite-layer

Whether overwriting the existing output vector layer is allowed.

--skip-errors

Added in version 3.12.

Whether failures to write feature(s) should be ignored. Note that this option sets the size of the transaction unit to one feature at a time, which may cause severe slowdown when inserting into databases.

--update

Whether to open an existing output dataset in update mode.

--upsert

Added in version 3.12.

Variant of *--append* where the *OGRLayer::UpsertFeature()* operation is used to insert or update features instead of appending with *OGRLayer::CreateFeature()*.

This is currently implemented only in a few drivers: *GPKG -- GeoPackage vector*, *Elasticsearch: Geographically Encoded Objects for Elasticsearch* and *MongoDBv3* (drivers that implement upsert expose the *GDAL_DCAP_UPSERT* capability).

The upsert operation uses the FID of the input feature, when it is set (and the FID column name is not the empty string), as the key to update existing features. It is crucial to make sure that the FID in the source and target layers are consistent.

For the GPKG driver, it is also possible to upsert features whose FID is unset or non-significant (the `--unset-fid` option of *gdal vector edit* can be used to ignore the FID from the source feature), when there is a UNIQUE column that is not the integer primary key.

Return status code

The program returns status code 0 in case of success, and non-zero in case of error (non-blocking errors emitted as warnings are considered as a successful execution).

Examples

Example 1: Change the type of a field given by its name to Integer

```
$ gdal vector set-field-type input.gpkg output.gpkg --field-name myfield --field-type␣
↪Integer
```

Example 2: Change the type of all fields of type Date to DateTime

```
$ gdal vector set-field-type input.gpkg output.gpkg --input-field-type Date --output-
↪field-type DateTime
```

5.1.4.34 gdal vector set-geom-type

Added in version 3.12.

Synopsis

```
Usage: gdal vector set-geom-type [OPTIONS] <INPUT> <OUTPUT>

Modify the geometry type of a vector dataset.

Positional arguments:

  --upsert                                                  Upsert features (implies 'append
↪') [not available in pipelines]
                                                            Mutually exclusive with --append
```

Description

gdal vector set-geom-type can be used to modify the geometry type of geometry fields at the layer and/or feature level.

It can also be used as a step of *gdal vector pipeline*.

The following groups of options can be combined together: - *--multi* / *--single* - *--linear* / *--curve* - *--dim*

GDALG output (on-the-fly / streamed dataset)

This program supports serializing the command line as a JSON file using the GDALG output format. The resulting file can then be opened as a vector dataset using the *GDALG: GDAL Streamed Algorithm* driver, and apply the specified pipeline in a on-the-fly / streamed way.

Program-Specific Options

--curve

Force geometries to curve geometry types. e.g. LINESTRING ==> COMPOUNDCURVE or POLYGON ==> CURVEPOLYGON. Points are kept unmodified. This option is mutually exclusive with *--linear*.

--dim

Force geometries to the specified dimension (XY, XYZ, XYM, or XYZM). If the input geometry lacks Z or M components, they will be set to 0. This option is mutually exclusive with *--geometry-type*.

--feature-only

Only modify the geometry type of features.

--geometry-type <GEOMETRY-TYPE>

Change the geometry type to be one of GEOMETRY, POINT, LINESTRING, POLYGON, MULTIPOINT, MULTILINESTRING, MULTIPOLYGON, GEOMETRYCOLLECTION, CURVE, CIRCULARSTRING, COMPOUNDCURVE, SURFACE, CURVEPOLYGON, MULTICURVE, MULTISURFACE, POLYHEDRALSURFACE or TIN. Z, M or ZM suffixes can be appended to the above values to indicate the dimensionality.

This option is mutually exclusive with *--multi*, *--single*, *--linear*, *--curve*, and *--dim*.

--layer-only

Only modify the layer geometry type. A typical use case is if the layer geometry type is set to unknown and the user knows that the layer only contains geometry of a given type.

--linear

Force geometries to linear/non-curve geometry types, approximating arcs with linear segments. The linear approximation can be controlled with configuration options *OGR_ARC_STEPSIZE* and *OGR_ARC_MAX_GAP* (specified using *vector_common_options --config*). e.g. COMPOUNDCURVE ==> LINESTRING. This option is mutually exclusive with *--curve*.

--multi

Force geometries to MULTI geometry types. e.g. POINT ==> MULTIPOINT. This option is mutually exclusive with *--single*.

--single

Force geometries to non-MULTI geometry types. e.g. MULTIPOINT ==> POINT. This option is mutually exclusive with *--multi*. MultiPoint or MultiLinestring with more than one component will be kept unmodified. MultiPolygon with more than one component will be merged into a (likely invalid according to OGC Simple Features rule) single polygon, merging all their rings.

--skip

Skip feature when change of feature geometry type failed (e.g. attempting to force a Point geometry type for a LineString geometry). Otherwise the source geometry will be kept unmodified (which may make it incompatible with the output layer if it does not support mix of geometry types). This option applies both when the target geometry type is defined with *--geometry-type*, or with any of *--multi*, *--single*, *--linear*, and *--curve*.

Standard Options

--active-geometry <ACTIVE-GEOMETRY>

Set the active geometry field from its name. When it is specified, only the specified geometry field will be subject to the processing. Other geometry fields will be not modified. If this option is not specified, all geometry fields will be subject to the processing. This option can be combined together with *--active-layer*.

--active-layer <ACTIVE-LAYER>

Set the active layer. When it is specified, only the layer specified by its name will be subject to the processing. Other layers will be not modified. If this option is not specified, all layers will be subject to the processing.

--append

Whether appending features to existing layer(s) is allowed. This also creates the output dataset if it does not exist yet.

--co, --creation-option <NAME>=<VALUE>

Many formats have one or more optional dataset creation options that can be used to control particulars about the file created. For instance, the GeoPackage driver supports creation options to control the version.

May be repeated.

The dataset creation options available vary by format driver, and some simple formats have no creation options at all. A list of options supported for a format can be listed with the *--formats* command line option but the documentation for the format is the definitive source of information on driver creation options. See *Vector drivers* format specific documentation for legal creation options for each format.

Note that dataset creation options are different from layer creation options.

--if, --input-format <format>

Format/driver name to be attempted to open the input file(s). It is generally not necessary to specify it, but it can be used to skip automatic driver detection, when it fails to select the appropriate driver. This option can be repeated several times to specify several candidate drivers. Note that it does not force those drivers to open the dataset. In particular, some drivers have requirements on file extensions.

May be repeated.

--input-layer <INPUT-LAYER>

Specifies the name of one or more layers to process. By default, all layers will be processed. To read and write all layers but only process a subset, use `--active-layer`.

--lco, --layer-creation-option <NAME>=<VALUE>

Many formats have one or more optional layer creation options that can be used to control particulars about the layer created. For instance, the GeoPackage driver supports layer creation options to control the feature identifier or geometry column name, setting the identifier or description, etc.

May be repeated.

The layer creation options available vary by format driver, and some simple formats have no layer creation options at all. A list of options supported for a format can be listed with the *--formats* command line option but the documentation for the format is the definitive source of information on driver creation options. See *Vector drivers* format specific documentation for legal creation options for each format.

Note that layer creation options are different from dataset creation options.

--oo, --open-option <NAME>=<VALUE>

Dataset open option (format specific).

May be repeated.

-f, --of, --format, --output-format <OUTPUT-FORMAT>

Which output vector format to use. Allowed values may be given by `gdal --formats | grep vector | grep rw | sort`

--output-layer <NAME>

Specifies the name of the layer to which features will be written. If not specified, output layer names will be the same as input layer names.

--output-open-option, --output-oo <NAME>=<VALUE>

Added in version 3.12.

Dataset open option for output dataset (format specific).

May be repeated.

--overwrite

Allow program to overwrite existing target file or dataset. Otherwise, by default, **gdal** errors out if the target file or dataset already exists.

--overwrite-layer

Whether overwriting the existing output vector layer is allowed.

--skip-errors

Added in version 3.12.

Whether failures to write feature(s) should be ignored. Note that this option sets the size of the transaction unit to one feature at a time, which may cause severe slowdown when inserting into databases.

--update

Whether to open an existing output dataset in update mode.

--upsert

Added in version 3.12.

Variant of *--append* where the *OGRLayer::UpsertFeature()* operation is used to insert or update features instead of appending with *OGRLayer::CreateFeature()*.

This is currently implemented only in a few drivers: *GPKG -- GeoPackage vector*, *Elasticsearch: Geographically Encoded Objects for Elasticsearch* and *MongoDBv3* (drivers that implement upsert expose the *GDAL_DCAP_UPSERT* capability).

The upsert operation uses the FID of the input feature, when it is set (and the FID column name is not the empty string), as the key to update existing features. It is crucial to make sure that the FID in the source and target layers are consistent.

For the GPKG driver, it is also possible to upsert features whose FID is unset or non-significant (the `--unset-fid` option of *gdal vector edit* can be used to ignore the FID from the source feature), when there is a UNIQUE column that is not the integer primary key.

Return status code

The program returns status code 0 in case of success, and non-zero in case of error (non-blocking errors emitted as warnings are considered as a successful execution).

Examples

Example 1: Convert a shapefile mixing polygons and multipolygons to a GeoPackage with multipolygons

```
$ gdal vector set-geom-type --geometry-type=MULTIPOLYGON in.shp out.gpkg --overwrite
```

Example 2: Convert a GeoPackage with curve geometries to a Shapefile (that does not support them)

```
$ gdal vector set-geom-type --linear in.gpkg out.shp --overwrite
```

5.1.4.35 gdal vector sort

Added in version 3.13.

Synopsis

```
Usage: gdal vector sort [OPTIONS] <INPUT> <OUTPUT>

Spatially order the features in a layer

```

Description

gdal vector sort sorts the features in a vector dataset according to the position of its geometries. The sorting method can be specified via *--method*, with Hilbert and Sort-Tile-Recursive (STRTree) algorithms available.

Features that have null or empty geometries will be placed at the end of the sorted dataset.

This command can also be used as a step of *gdal vector pipeline*.

> **Note**
>
> Use of the STRtree algorithm requires a GDAL build against the GEOS library.

Program-Specific Options

--geometry-field <GEOMETRY-FIELD>

The name of the geometry field by which features should be sorted.

--method <METHOD>

Specifies the sorting method. Available options are:

- hilbert : default method. Geometries are sorted according to the Hilbert code of the center point of their bounding box
- strtree : Geometries are sorted by constructing a sort-tile-recursive tree using the GEOS library and performing a depth-first iteration.

--use-tempfile

Write the input features to a temporary file from which they can be read in sorted order. Avoids the need to load the entire input layer into memory.

Return status code

The program returns status code 0 in case of success, and non-zero in case of error (non-blocking errors emitted as warnings are considered as a successful execution).

Examples

Example 1: Create a cloud-optimized Shapefile

```
$ gdal vector sort in.gpkg out.shp --method hilbert --lco SPATIAL_INDEX=YES
```

5.1.4.36 gdal vector simplify

Added in version 3.12.

Synopsis

```
Usage: gdal vector simplify [OPTIONS] <INPUT> <OUTPUT> <TOLERANCE>

```

Description

gdal vector simplify simplifies geometries, ensuring that the result is a valid geometry having the same dimension and number of components as the input.

The simplification uses a maximum distance difference algorithm similar to the one used in the Douglas-Peucker algorithm.

This done by the *OGRGeometry::SimplifyPreserveTopology()* method which preserves the topology per feature, but not for a whole layer. Thus gaps or overlaps between geometries that were initially contiguous may happen. To perform simplification that preserves shared boundaries between geometries, see *gdal vector simplify-coverage*.

This command can also be used as a step of *gdal vector pipeline*.

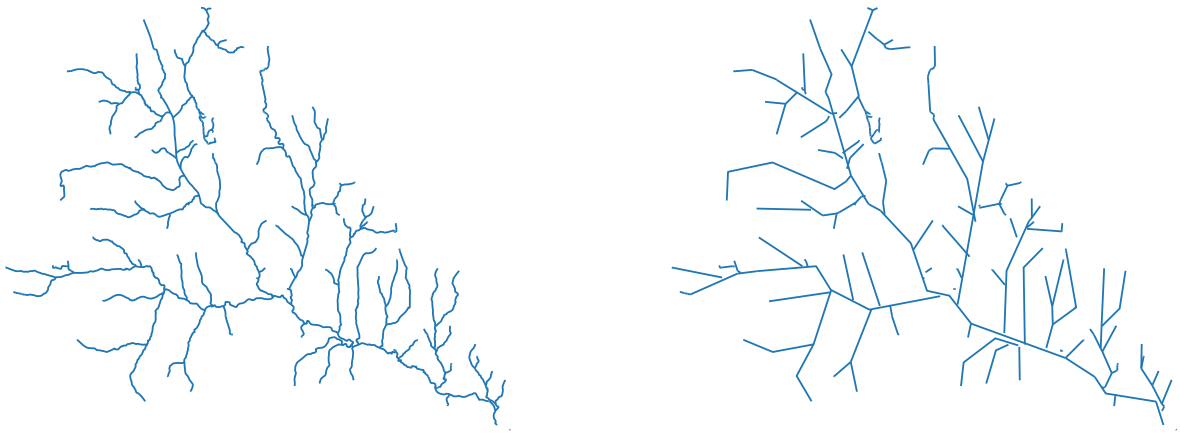

Fig. 15: Line dataset before (left) and after (right) simplification with **gdal vector simplify**.

> **Note**
>
> This command requires a GDAL build against the GEOS library.

GDALG output (on-the-fly / streamed dataset)

This program supports serializing the command line as a JSON file using the `GDALG` output format. The resulting file can then be opened as a vector dataset using the *GDALG: GDAL Streamed Algorithm* driver, and apply the specified pipeline in a on-the-fly / streamed way.

Program-Specific Options

--tolerance <TOLERANCE>

The specified value of this option is the tolerance used to merge consecutive points of the output geometry using the *OGRGeometry::SimplifyPreserveTopology()* method The unit of the distance is in georeferenced units of the source layer.

Standard Options

--active-geometry <ACTIVE-GEOMETRY>

Set the active geometry field from its name. When it is specified, only the specified geometry field will be subject to the processing. Other geometry fields will be not modified. If this option is not specified, all geometry fields will be subject to the processing. This option can be combined together with *--active-layer*.

--active-layer <ACTIVE-LAYER>

Set the active layer. When it is specified, only the layer specified by its name will be subject to the processing. Other layers will be not modified. If this option is not specified, all layers will be subject to the processing.

--append

Whether appending features to existing layer(s) is allowed. This also creates the output dataset if it does not exist yet.

--co, --creation-option <NAME>=<VALUE>

Many formats have one or more optional dataset creation options that can be used to control particulars about the file created. For instance, the GeoPackage driver supports creation options to control the version.

May be repeated.

The dataset creation options available vary by format driver, and some simple formats have no creation options at all. A list of options supported for a format can be listed with the *--formats* command line option but the documentation for the format is the definitive source of information on driver creation options. See *Vector drivers* format specific documentation for legal creation options for each format.

Note that dataset creation options are different from layer creation options.

--if, --input-format <format>

Format/driver name to be attempted to open the input file(s). It is generally not necessary to specify it, but it can be used to skip automatic driver detection, when it fails to select the appropriate driver. This option can be repeated several times to specify several candidate drivers. Note that it does not force those drivers to open the dataset. In particular, some drivers have requirements on file extensions.

May be repeated.

--input-layer <INPUT-LAYER>

Specifies the name of one or more layers to process. By default, all layers will be processed. To read and write all layers but only process a subset, use *--active-layer*.

--lco, --layer-creation-option <NAME>=<VALUE>

Many formats have one or more optional layer creation options that can be used to control particulars about the layer created. For instance, the GeoPackage driver supports layer creation options to control the feature identifier or geometry column name, setting the identifier or description, etc.

May be repeated.

The layer creation options available vary by format driver, and some simple formats have no layer creation options at all. A list of options supported for a format can be listed with the *--formats* command line option but the documentation for the format is the definitive source of information on driver creation options. See *Vector drivers* format specific documentation for legal creation options for each format.

Note that layer creation options are different from dataset creation options.

--oo, --open-option <NAME>=<VALUE>

Dataset open option (format specific).

May be repeated.

-f, --of, --format, --output-format <OUTPUT-FORMAT>

Which output vector format to use. Allowed values may be given by `gdal --formats | grep vector | grep rw | sort`

--output-layer <NAME>

Specifies the name of the layer to which features will be written. If not specified, output layer names will be the same as input layer names.

--output-open-option, --output-oo <NAME>=<VALUE>

Added in version 3.12.

Dataset open option for output dataset (format specific).

May be repeated.

--overwrite

Allow program to overwrite existing target file or dataset. Otherwise, by default, **gdal** errors out if the target file or dataset already exists.

--overwrite-layer

Whether overwriting the existing output vector layer is allowed.

--skip-errors

Added in version 3.12.

Whether failures to write feature(s) should be ignored. Note that this option sets the size of the transaction unit to one feature at a time, which may cause severe slowdown when inserting into databases.

--update

Whether to open an existing output dataset in update mode.

--upsert

Added in version 3.12.

Variant of *--append* where the *OGRLayer::UpsertFeature()* operation is used to insert or update features instead of appending with *OGRLayer::CreateFeature()*.

This is currently implemented only in a few drivers: *GPKG -- GeoPackage vector*, *Elasticsearch: Geographically Encoded Objects for Elasticsearch* and *MongoDBv3* (drivers that implement upsert expose the *GDAL_DCAP_UPSERT* capability).

The upsert operation uses the FID of the input feature, when it is set (and the FID column name is not the empty string), as the key to update existing features. It is crucial to make sure that the FID in the source and target layers are consistent.

For the GPKG driver, it is also possible to upsert features whose FID is unset or non-significant (the `--unset-fid` option of *gdal vector edit* can be used to ignore the FID from the source feature), when there is a UNIQUE column that is not the integer primary key.

Return status code

The program returns status code 0 in case of success, and non-zero in case of error (non-blocking errors emitted as warnings are considered as a successful execution).

Examples

Example 1: Simplify geometries using a tolerance of one km (assuming the CRS is in meters)

```
$ gdal vector simplify --tolerance=1000 in.gpkg out.gpkg --overwrite
```

5.1.4.37 gdal vector simplify-coverage

Added in version 3.12.

Synopsis

```
Usage: gdal vector simplify-coverage [OPTIONS] <INPUT> <OUTPUT> <TOLERANCE>

Simplify shared boundaries of a polygonal vector dataset.

Positional arguments:

↪') [not available in pipelines]
                                                         Mutually exclusive with --append
```

Description

gdal vector simplify-coverage simplifies boundaries of a polygonal dataset, such that shared boundaries are preserved without introducing gaps or overlaps between features. Gaps or overlaps already present in the input dataset will not be corrected.

This requires loading the entire dataset into memory at once. If preservation of shared boundaries is not needed, *gdal vector simplify* provides an alternative that can process geometries in a streaming manner.

Simplification is performed using the Visvalingam-Whyatt algorithm.

This command can also be used as a step of *gdal vector pipeline*.

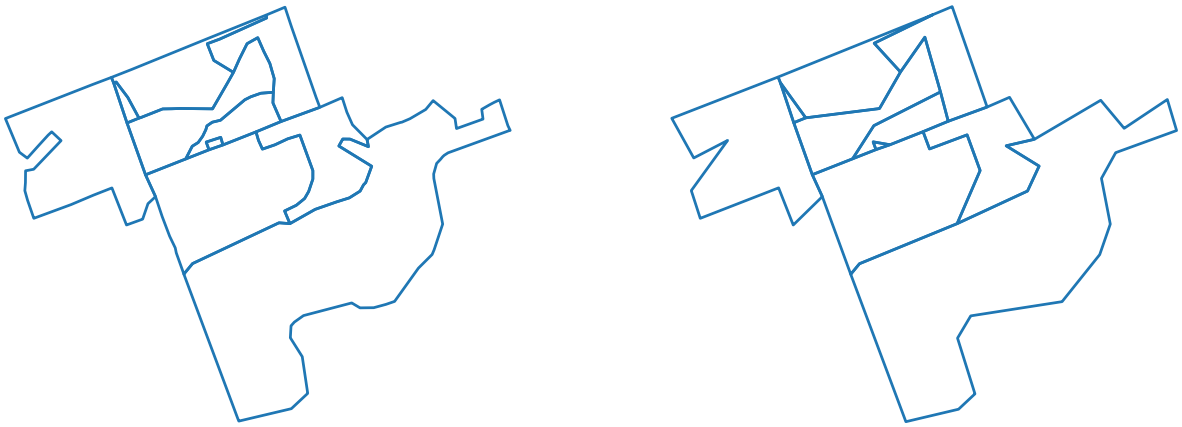

Fig. 16: Polygon dataset before (left) and after (right) simplification with **gdal vector simplify-coverage**.

> **Note**
>
> This command requires a GDAL build against the GEOS library (version 3.12 or greater).

GDALG output (on-the-fly / streamed dataset)

This program supports serializing the command line as a JSON file using the `GDALG` output format. The resulting file can then be opened as a vector dataset using the *GDALG: GDAL Streamed Algorithm* driver, and apply the specified pipeline in a on-the-fly / streamed way.

> **Note**
>
> However this algorithm is not natively streaming compatible. Consequently a in-memory temporary dataset will be generated, which may cause significant processing time at opening.

Program-Specific Options

--preserve-boundary

Flag indicating whether to preserve (avoid simplifying) external boundaries. This can be useful when simplifying a portion of a larger dataset.

--tolerance <TOLERANCE>

Tolerance used for determining whether vertices should be removed. Specified in georeferenced units of the source layer.

Standard Options

--active-layer <ACTIVE-LAYER>

Set the active layer. When it is specified, only the layer specified by its name will be subject to the processing. Other layers will be not modified. If this option is not specified, all layers will be subject to the processing.

--append

Whether appending features to existing layer(s) is allowed. This also creates the output dataset if it does not exist yet.

--co, --creation-option <NAME>=<VALUE>

Many formats have one or more optional dataset creation options that can be used to control particulars about the file created. For instance, the GeoPackage driver supports creation options to control the version.

May be repeated.

The dataset creation options available vary by format driver, and some simple formats have no creation options at all. A list of options supported for a format can be listed with the *--formats* command line option but the documentation for the format is the definitive source of information on driver creation options. See *Vector drivers* format specific documentation for legal creation options for each format.

Note that dataset creation options are different from layer creation options.

--if, --input-format <format>

Format/driver name to be attempted to open the input file(s). It is generally not necessary to specify it, but it can be used to skip automatic driver detection, when it fails to select the appropriate driver. This option can be repeated several times to specify several candidate drivers. Note that it does not force those drivers to open the dataset. In particular, some drivers have requirements on file extensions.

May be repeated.

--input-layer <INPUT-LAYER>

Specifies the name of one or more layers to process. By default, all layers will be processed. To read and write all layers but only process a subset, use `--active-layer`.

--lco, --layer-creation-option <NAME>=<VALUE>

Many formats have one or more optional layer creation options that can be used to control particulars about the layer created. For instance, the GeoPackage driver supports layer creation options to control the feature identifier or geometry column name, setting the identifier or description, etc.

May be repeated.

The layer creation options available vary by format driver, and some simple formats have no layer creation options at all. A list of options supported for a format can be listed with the *--formats* command line option but the documentation for the format is the definitive source of information on driver creation options. See *Vector drivers* format specific documentation for legal creation options for each format.

Note that layer creation options are different from dataset creation options.

--oo, --open-option <NAME>=<VALUE>

Dataset open option (format specific).

May be repeated.

-f, --of, --format, --output-format <OUTPUT-FORMAT>

Which output vector format to use. Allowed values may be given by `gdal --formats | grep vector | grep rw | sort`

--output-layer <NAME>

Specifies the name of the layer to which features will be written. If not specified, output layer names will be the same as input layer names.

--output-open-option, --output-oo <NAME>=<VALUE>

Added in version 3.12.

Dataset open option for output dataset (format specific).

May be repeated.

--overwrite

Allow program to overwrite existing target file or dataset. Otherwise, by default, **gdal** errors out if the target file or dataset already exists.

--overwrite-layer

Whether overwriting the existing output vector layer is allowed.

--skip-errors

Added in version 3.12.

Whether failures to write feature(s) should be ignored. Note that this option sets the size of the transaction unit to one feature at a time, which may cause severe slowdown when inserting into databases.

--update

Whether to open an existing output dataset in update mode.

--upsert

Added in version 3.12.

Variant of `--append` where the *OGRLayer::UpsertFeature()* operation is used to insert or update features instead of appending with *OGRLayer::CreateFeature()*.

This is currently implemented only in a few drivers: *GPKG -- GeoPackage vector*, *Elasticsearch: Geographically Encoded Objects for Elasticsearch* and *MongoDBv3* (drivers that implement upsert expose the *GDAL_DCAP_UPSERT* capability).

The upsert operation uses the FID of the input feature, when it is set (and the FID column name is not the empty string), as the key to update existing features. It is crucial to make sure that the FID in the source and target layers are consistent.

For the GPKG driver, it is also possible to upsert features whose FID is unset or non-significant (the `--unset-fid` option of *gdal vector edit* can be used to ignore the FID from the source feature), when there is a UNIQUE column that is not the integer primary key.

Return status code

The program returns status code 0 in case of success, and non-zero in case of error (non-blocking errors emitted as warnings are considered as a successful execution).

Examples

Example 1: Simplify geometries using a tolerance of one square meter (assuming the CRS is in meters)

```
$ gdal vector simplify-coverage --tolerance=1 in.gpkg out.gpkg --overwrite
```

Example 2: Using simplify-coverage as part of a vector pipeline

This can be used to make the output geometries have a consistent type.

```
$ gdal vector pipeline ! read tl_2024_us_state.shp ! simplify-coverage --tolerance 2 !␣
↪set-geom-type --multi ! write out.gpkg --overwrite
```

5.1.4.38 gdal vector sql

Added in version 3.11.

Synopsis

```
Usage: gdal vector sql [OPTIONS] <INPUT> [<OUTPUT>]

Apply SQL statement(s) to a dataset.

Positional arguments:
  -i, --dataset, --input <INPUT>                      Input vector datasets [required]␣
↪[not available in pipelines]
  -o, --output <OUTPUT>                               Output vector dataset [not␣
↪available in pipelines]

Common Options:
  -h, --help                                          Display help message and exit
  --json-usage                                        Display usage as JSON document␣
↪and exit
  --config <KEY>=<VALUE>                              Configuration option [may be␣
↪repeated]
  -q, --quiet                                         Quiet mode (no progress bar or␣
↪warning message) [not available in pipelines]

Options:
```

                                                       Mutually exclusive with --upsert
  --skip-errors                                        Skip errors when writing features␣
↪[not available in pipelines]
  --sql <statement>|@<filename>                        SQL statement(s) [may be␣
↪repeated] [required]
  --output-layer <OUTPUT-LAYER>                        Output layer name(s) [may be␣
↪repeated]
  --dialect <DIALECT>                                  SQL dialect (e.g. OGRSQL, SQLITE)

Advanced Options:
  --if, --input-format <INPUT-FORMAT>                  Input formats [may be repeated]␣
↪[not available in pipelines]
  --oo, --open-option <KEY>=<VALUE>                    Open options [may be repeated]␣
↪[not available in pipelines]
  --output-oo, --output-open-option <KEY>=<VALUE>      Output open options [may be␣
↪repeated] [not available in pipelines]
  --upsert                                             Upsert features (implies 'append
↪') [not available in pipelines]
                                                       Mutually exclusive with --append
```

Description

gdal vector sql returns one or several layers evaluated from SQL statements.

Starting with GDAL 3.12, when using `--update`, and without an output dataset specified, this can be used to execute statements that modify the input dataset, such as UPDATE, DELETE, etc.

GDALG output (on-the-fly / streamed dataset)

This program supports serializing the command line as a JSON file using the `GDALG` output format. The resulting file can then be opened as a vector dataset using the *GDALG: GDAL Streamed Algorithm* driver, and apply the specified pipeline in a on-the-fly / streamed way.

Program-Specific Options

--output-layer <OUTPUT-LAYER>

Output SQL layer name(s). If not specified, a generic layer name such as "SELECT" may be generated.

Must be specified as many times as there are SQL statements, either as several --output-layer arguments, or a single one with the layer names combined with comma.

--quiet

Added in version 3.12.

Silence potential information messages.

--sql <sql_statement>|@<filename>

SQL statement to execute that returns a table/layer (typically a SELECT statement).

Can be repeated to generated multiple output layers (repeating --sql <value> for each output layer)

--dialect <DIALECT>

SQL dialect.

By default the native SQL of an RDBMS is used when using `gdal vector sql`. If using `sql` as a step of `gdal vector pipeline`, this is only true if the step preceding `sql` is `read`, otherwise the *OGRSQL* dialect is used.

If a datasource does not support SQL natively, the default is to use the `OGRSQL` dialect, which can also be specified with any data source.

The *SQL SQLite dialect* dialect can be chosen with the `SQLITE` and `INDIRECT_SQLITE` dialect values, and this can be used with any data source. Overriding the default dialect may be beneficial because the capabilities of the SQL dialects vary.

Supported dialects can be checked with `gdal --format`. For example:

```
$ gdal --format "PostgreSQL"
[...]
Supported SQL dialects: NATIVE OGRSQL SQLITE
[...]

$ gdal --format "ESRI Shapefile"
[...]
Supported SQL dialects: OGRSQL SQLITE
[...]
```

Standard Options

--append

Whether appending features to existing layer(s) is allowed. This also creates the output dataset if it does not exist yet.

--co, --creation-option <NAME>=<VALUE>

Many formats have one or more optional dataset creation options that can be used to control particulars about the file created. For instance, the GeoPackage driver supports creation options to control the version.

May be repeated.

The dataset creation options available vary by format driver, and some simple formats have no creation options at all. A list of options supported for a format can be listed with the *--formats* command line option but the documentation for the format is the definitive source of information on driver creation options. See *Vector drivers* format specific documentation for legal creation options for each format.

Note that dataset creation options are different from layer creation options.

--if, --input-format <format>

Format/driver name to be attempted to open the input file(s). It is generally not necessary to specify it, but it can be used to skip automatic driver detection, when it fails to select the appropriate driver. This option can be repeated several times to specify several candidate drivers. Note that it does not force those drivers to open the dataset. In particular, some drivers have requirements on file extensions.

May be repeated.

--lco, --layer-creation-option <NAME>=<VALUE>

Many formats have one or more optional layer creation options that can be used to control particulars about the layer created. For instance, the GeoPackage driver supports layer creation options to control the feature identifier or geometry column name, setting the identifier or description, etc.

May be repeated.

The layer creation options available vary by format driver, and some simple formats have no layer creation options at all. A list of options supported for a format can be listed with the *--formats* command line option but the documentation for the format is the definitive source of information on driver creation options. See *Vector drivers* format specific documentation for legal creation options for each format.

Note that layer creation options are different from dataset creation options.

--oo, --open-option <NAME>=<VALUE>

Dataset open option (format specific).

May be repeated.

-f, --of, --format, --output-format <OUTPUT-FORMAT>

Which output vector format to use. Allowed values may be given by `gdal --formats | grep vector | grep rw | sort`

--output-open-option, --output-oo <NAME>=<VALUE>

Added in version 3.12.

Dataset open option for output dataset (format specific).

May be repeated.

--overwrite

Allow program to overwrite existing target file or dataset. Otherwise, by default, **gdal** errors out if the target file or dataset already exists.

--overwrite-layer

Whether overwriting the existing output vector layer is allowed.

--skip-errors

Added in version 3.12.

Whether failures to write feature(s) should be ignored. Note that this option sets the size of the transaction unit to one feature at a time, which may cause severe slowdown when inserting into databases.

--update

Whether to open an existing output dataset in update mode.

--upsert

Added in version 3.12.

Variant of *--append* where the *OGRLayer::UpsertFeature()* operation is used to insert or update features instead of appending with *OGRLayer::CreateFeature()*.

This is currently implemented only in a few drivers: *GPKG -- GeoPackage vector*, *Elasticsearch: Geographically Encoded Objects for Elasticsearch* and *MongoDBv3* (drivers that implement upsert expose the *GDAL_DCAP_UPSERT* capability).

The upsert operation uses the FID of the input feature, when it is set (and the FID column name is not the empty string), as the key to update existing features. It is crucial to make sure that the FID in the source and target layers are consistent.

For the GPKG driver, it is also possible to upsert features whose FID is unset or non-significant (the `--unset-fid` option of *gdal vector edit* can be used to ignore the FID from the source feature), when there is a UNIQUE column that is not the integer primary key.

-q, --quiet

Suppress progress bar and some warning messages.

Return status code

The program returns status code 0 in case of success, and non-zero in case of error (non-blocking errors emitted as warnings are considered as a successful execution).

Examples

Example 1: Generate a GeoPackage file with a layer sorted by descending population

```
$ gdal vector sql in.gpkg out.gpkg --output-layer country_sorted_by_pop --sql="SELECT *␣
↪FROM country ORDER BY pop DESC"
```

Example 2: Generate a GeoPackage file with 2 SQL result layers

```
$ gdal vector sql in.gpkg out.gpkg --output-layer=beginning,end --sql="SELECT * FROM my_
↪layer LIMIT 100" --sql="SELECT * FROM my_layer OFFSET 100000 LIMIT 100"
```

Example 3: Modify in-place a GeoPackage dataset

```
$ gdal vector sql --update my.gpkg --sql "DELETE FROM countries WHERE pop > 1e6"
```

Example 4: Add a new field to an existing layer of a GeoPackage

```
$ gdal vector sql --update my.gpkg --sql "ALTER TABLE countries ADD COLUMN abbrev␣
↪STRING(10)"
```

Example 5: Append to an existing layer of a GeoPackage file

```
$ gdal vector pipeline read europe.gpkg ! \
                       sql --sql "SELECT * FROM country WHERE pop > 1e6" ! \
                       write --append --output-layer-name=world world.gpkg
```

Example 6: List unique values in a Shapefile field

Bash

PowerShell

```
gdal vector pipeline \
    ! read in.shp \
    ! sql --sql "SELECT DISTINCT CODE FROM in ORDER BY CODE" \
    ! info --features
```

```
gdal vector pipeline `
    ! read in.shp `
    ! sql --sql "SELECT DISTINCT CODE FROM in ORDER BY CODE" `
    ! info --features
```

5.1.4.39 gdal vector swap-xy

Added in version 3.12.

Synopsis

```
Usage: gdal vector swap-xy [OPTIONS] <INPUT> <OUTPUT>

Swap X and Y coordinates of geometries of a vector dataset.

Positional arguments:
  -i, --input <INPUT>                                    Input vector datasets [required]␣
↪[not available in pipelines]
  -o, --output <OUTPUT>                                  Output vector dataset [required]␣
↪[not available in pipelines]

Common Options:
  -h, --help                                             Display help message and exit
  --json-usage                                           Display usage as JSON document␣
↪and exit
  --config <KEY>=<VALUE>                                 Configuration option [may be␣
↪repeated]
  -q, --quiet                                            Quiet mode (no progress bar or␣
↪warning message) [not available in pipelines]

Options:
  -l, --layer, --input-layer <INPUT-LAYER>               Input layer name(s) [may be␣
↪repeated] [not available in pipelines]
  -f, --of, --format, --output-format <OUTPUT-FORMAT>  Output format ("GDALG" allowed)␣
↪[not available in pipelines]
  --co, --creation-option <KEY>=<VALUE>                  Creation option [may be repeated]␣
↪[not available in pipelines]
  --lco, --layer-creation-option <KEY>=<VALUE>           Layer creation option [may be␣
↪repeated] [not available in pipelines]
  --overwrite                                            Whether overwriting existing␣
↪output dataset is allowed [not available in pipelines]
  --update                                               Whether to open existing dataset␣
↪in update mode [not available in pipelines]
  --overwrite-layer                                      Whether overwriting existing␣
↪output layer is allowed [not available in pipelines]
  --append                                               Whether appending to existing␣
↪layer is allowed [not available in pipelines]
```

(continues on next page)

(continued from previous page)

↪repeated] [not available in pipelines]
  --upsert                                              Upsert features (implies 'append
↪') [not available in pipelines]
                                                        Mutually exclusive with --append
```

Description

gdal vector swap-xy swaps the X and Y coordinates of geometries, typically to work around axis order issues of coordinate reference systems.

It can also be used as a step of *gdal vector pipeline*.

GDALG output (on-the-fly / streamed dataset)

This program supports serializing the command line as a JSON file using the `GDALG` output format. The resulting file can then be opened as a vector dataset using the *GDALG: GDAL Streamed Algorithm* driver, and apply the specified pipeline in a on-the-fly / streamed way.

Standard Options

--active-geometry <ACTIVE-GEOMETRY>

Set the active geometry field from its name. When it is specified, only the specified geometry field will be subject to the processing. Other geometry fields will be not modified. If this option is not specified, all geometry fields will be subject to the processing. This option can be combined together with `--active-layer`.

--active-layer <ACTIVE-LAYER>

Set the active layer. When it is specified, only the layer specified by its name will be subject to the processing. Other layers will be not modified. If this option is not specified, all layers will be subject to the processing.

--append

Whether appending features to existing layer(s) is allowed. This also creates the output dataset if it does not exist yet.

--co, --creation-option <NAME>=<VALUE>

Many formats have one or more optional dataset creation options that can be used to control particulars about the file created. For instance, the GeoPackage driver supports creation options to control the version.

May be repeated.

The dataset creation options available vary by format driver, and some simple formats have no creation options at all. A list of options supported for a format can be listed with the *--formats* command line option but the documentation for the format is the definitive source of information on driver creation options. See *Vector drivers* format specific documentation for legal creation options for each format.

Note that dataset creation options are different from layer creation options.

--if, --input-format <format>

Format/driver name to be attempted to open the input file(s). It is generally not necessary to specify it, but it can be used to skip automatic driver detection, when it fails to select the appropriate driver. This option can be repeated several times to specify several candidate drivers. Note that it does not force those drivers to open the dataset. In particular, some drivers have requirements on file extensions.

May be repeated.

--input-layer <INPUT-LAYER>

Specifies the name of one or more layers to process. By default, all layers will be processed. To read and write all layers but only process a subset, use `--active-layer`.

--lco, --layer-creation-option <NAME>=<VALUE>

Many formats have one or more optional layer creation options that can be used to control particulars about the layer created. For instance, the GeoPackage driver supports layer creation options to control the feature identifier or geometry column name, setting the identifier or description, etc.

May be repeated.

The layer creation options available vary by format driver, and some simple formats have no layer creation options at all. A list of options supported for a format can be listed with the *--formats* command line option but the documentation for the format is the definitive source of information on driver creation options. See *Vector drivers* format specific documentation for legal creation options for each format.

Note that layer creation options are different from dataset creation options.

--oo, --open-option <NAME>=<VALUE>

Dataset open option (format specific).

May be repeated.

-f, --of, --format, --output-format <OUTPUT-FORMAT>

Which output vector format to use. Allowed values may be given by `gdal --formats | grep vector | grep rw | sort`

--output-layer <NAME>

Specifies the name of the layer to which features will be written. If not specified, output layer names will be the same as input layer names.

--output-open-option, --output-oo <NAME>=<VALUE>

Added in version 3.12.

Dataset open option for output dataset (format specific).

May be repeated.

--overwrite

Allow program to overwrite existing target file or dataset. Otherwise, by default, **gdal** errors out if the target file or dataset already exists.

--overwrite-layer

Whether overwriting the existing output vector layer is allowed.

--skip-errors

Added in version 3.12.

Whether failures to write feature(s) should be ignored. Note that this option sets the size of the transaction unit to one feature at a time, which may cause severe slowdown when inserting into databases.

--update

Whether to open an existing output dataset in update mode.

--upsert

Added in version 3.12.

Variant of *--append* where the *OGRLayer::UpsertFeature()* operation is used to insert or update features instead of appending with *OGRLayer::CreateFeature()*.

This is currently implemented only in a few drivers: *GPKG -- GeoPackage vector*, *Elasticsearch: Geographically Encoded Objects for Elasticsearch* and *MongoDBv3* (drivers that implement upsert expose the *GDAL_DCAP_UPSERT* capability).

The upsert operation uses the FID of the input feature, when it is set (and the FID column name is not the empty string), as the key to update existing features. It is crucial to make sure that the FID in the source and target layers are consistent.

For the GPKG driver, it is also possible to upsert features whose FID is unset or non-significant (the `--unset-fid` option of *gdal vector edit* can be used to ignore the FID from the source feature), when there is a UNIQUE column that is not the integer primary key.

Return status code

The program returns status code 0 in case of success, and non-zero in case of error (non-blocking errors emitted as warnings are considered as a successful execution).

Examples

Example 1: Basic usage

```
$ gdal vector swap-xy in.gpkg out.gpkg --overwrite
```

5.1.4.40 gdal vector update

Added in version 3.13.

Synopsis

```
Usage: gdal vector update [OPTIONS] <INPUT> <OUTPUT>

Update an existing vector dataset with an input vector dataset.

Positional arguments:
  -i, --input <INPUT>                             Input vector datasets [required] [not␣
↪available in pipelines]
  -o, --output <OUTPUT>                           Output vector dataset [required]

Common Options:
  -h, --help                                      Display help message and exit
```

(continues on next page)

(continued from previous page)

```
  --json-usage                                      Display usage as JSON document and␣
↪exit
  --config <KEY>=<VALUE>                            Configuration option [may be repeated]
  -q, --quiet                                       Quiet mode (no progress bar or␣
↪warning message) [not available in pipelines]

Options:
  --input-layer <INPUT-LAYER>                       Input layer name
  --output-layer <OUTPUT-LAYER>                     Output layer name
  --mode <MODE>                                     Set update mode. MODE=merge|update-
↪only|append-only (default: merge)
  --key <KEY>                                       Field(s) used as a key to identify␣
↪features [may be repeated]

Advanced Options:
  --if, --input-format <INPUT-FORMAT>               Input formats [may be repeated] [not␣
↪available in pipelines]
  --oo, --open-option <KEY>=<VALUE>                 Open options [may be repeated] [not␣
↪available in pipelines]
  --output-oo, --output-open-option <KEY>=<VALUE>  Output open options [may be repeated]
```

Description

gdal vector update can be used to update the features of an existing output vector dataset with the features of the input vector. It identifies matching features between input and output based on their feature ID by default, or based on the value of one or several columns forming a key, when using *--key*.

With the default `merge` mode, features found in both layers will be updated, and features only existing in the input layer will be created in the output layer.

The schemas of the input and output layers do not need to be identical (except on columns specified by *--key*), but they should use the same CRS for geometry columns, as no on-the-fly reprojection is done. If a column exists in the input layer but not in the output layer, it will not be created. And if a column exists in the output layer and not in the input layer, its content will not be updated.

gdal vector update can be used as a step of a pipeline, with the input dataset being the output of the previous step.

Program-Specific Options

--input-layer `<INPUT-LAYER>`

Input layer name. Must be specified if the input dataset has several layers.

--key `<KEY>`

Field(s) used as a key to identify features. For multiple fields, specify *--key* multiple times.

--mode `merge|update-only|append-only`

Defines how updates are done. Default is `merge`.

When using the default `merge` mode, features found in both layers will be updated, and features only existing in the input layer will be created in the output layer.

When using the `update-only` mode, features found in both layers will be updated, and features only found in the input layer will be ignored.

When using the `append-only` mode, features found in both layers will *not* be updated, and features only found in the input layer will be created in the output layer.

--output-layer <OUTPUT-LAYER>

Output layer name. Must be specified if the output dataset has several layers.

Standard Options

--if, --input-format <format>

Format/driver name to be attempted to open the input file(s). It is generally not necessary to specify it, but it can be used to skip automatic driver detection, when it fails to select the appropriate driver. This option can be repeated several times to specify several candidate drivers. Note that it does not force those drivers to open the dataset. In particular, some drivers have requirements on file extensions.

May be repeated.

--oo, --open-option <NAME>=<VALUE>

Dataset open option (format specific).

May be repeated.

--output-open-option, --output-oo <NAME>=<VALUE>

Added in version 3.12.

Dataset open option for output dataset (format specific).

May be repeated.

Return status code

The program returns status code 0 in case of success, and non-zero in case of error (non-blocking errors emitted as warnings are considered as a successful execution).

Examples

Example 1: Update existing out.gpkg with content of in.gpkg, using identifier as the key.

```
$ gdal vector update --key identifier in.gpkg out.gpkg
```

5.1.4.41 gdal vector pipeline write

Added in version 3.11.

Description

The `write` operation is for use in a *gdal pipeline* only, and writes a vector dataset. This is the last step of a pipeline.

To write a temporary dataset in the middle of a pipeline, use *gdal vector materialize*.

Synopsis

```
* write [OPTIONS] <OUTPUT>
--------------------------

Write a vector dataset.

Positional arguments:
  -o, --output <OUTPUT>                                Output vector dataset [required]
```

(continues on next page)

(continued from previous page)

```
Options:
  -f, --of, --format, --output-format <OUTPUT-FORMAT>  Output format ("GDALG" allowed)
  --co, --creation-option <KEY>=<VALUE>                Creation option [may be repeated]
  --lco, --layer-creation-option <KEY>=<VALUE>         Layer creation option [may be␣
↪repeated]
  --overwrite                                          Whether overwriting existing␣
↪output dataset is allowed
  --update                                             Whether to open existing dataset␣
↪in update mode
  --overwrite-layer                                    Whether overwriting existing␣
↪output layer is allowed
  --append                                             Whether appending to existing␣
↪layer is allowed
                                                       Mutually exclusive with --upsert
  -l, --output-layer <OUTPUT-LAYER>                    Output layer name
  --skip-errors                                        Skip errors when writing features
  --no-create-empty-layers                             Avoid creating layers to which no␣
↪features will be written

Advanced Options:
  --output-oo, --output-open-option <KEY>=<VALUE>      Output open options [may be␣
↪repeated]
  --upsert                                             Upsert features (implies 'append')
                                                       Mutually exclusive with --append
```

Standard Options

-f, --of, --format, --output-format <OUTPUT-FORMAT>

Which output vector format to use. Allowed values may be given by `gdal --formats | grep vector | grep rw | sort`

--co, --creation-option <NAME>=<VALUE>

Many formats have one or more optional dataset creation options that can be used to control particulars about the file created. For instance, the GeoPackage driver supports creation options to control the version.

May be repeated.

The dataset creation options available vary by format driver, and some simple formats have no creation options at all. A list of options supported for a format can be listed with the *--formats* command line option but the documentation for the format is the definitive source of information on driver creation options. See *Vector drivers* format specific documentation for legal creation options for each format.

Note that dataset creation options are different from layer creation options.

--lco, --layer-creation-option <NAME>=<VALUE>

Many formats have one or more optional layer creation options that can be used to control particulars about the layer created. For instance, the GeoPackage driver supports layer creation options to control the feature identifier or geometry column name, setting the identifier or description, etc.

May be repeated.

The layer creation options available vary by format driver, and some simple formats have no layer creation options at all. A list of options supported for a format can be listed with the *--formats* command line option but the

documentation for the format is the definitive source of information on driver creation options. See *Vector drivers* format specific documentation for legal creation options for each format.

Note that layer creation options are different from dataset creation options.

--overwrite

Allow program to overwrite existing target file or dataset. Otherwise, by default, **gdal** errors out if the target file or dataset already exists.

--update

Whether to open an existing output dataset in update mode.

--overwrite-layer

Whether overwriting the existing output vector layer is allowed.

--append

Whether appending features to existing layer(s) is allowed. This also creates the output dataset if it does not exist yet.

--output-layer <NAME>

Specifies the name of the layer to which features will be written. If not specified, output layer names will be the same as input layer names.

--output-open-option, --output-oo <NAME>=<VALUE>

Added in version 3.12.

Dataset open option for output dataset (format specific).

May be repeated.

--skip-errors

Added in version 3.12.

Whether failures to write feature(s) should be ignored. Note that this option sets the size of the transaction unit to one feature at a time, which may cause severe slowdown when inserting into databases.

--upsert

Added in version 3.12.

Variant of `--append` where the *OGRLayer::UpsertFeature()* operation is used to insert or update features instead of appending with *OGRLayer::CreateFeature()*.

This is currently implemented only in a few drivers: *GPKG -- GeoPackage vector*, *Elasticsearch: Geographically Encoded Objects for Elasticsearch* and *MongoDBv3* (drivers that implement upsert expose the *GDAL_DCAP_UPSERT* capability).

The upsert operation uses the FID of the input feature, when it is set (and the FID column name is not the empty string), as the key to update existing features. It is crucial to make sure that the FID in the source and target layers are consistent.

For the GPKG driver, it is also possible to upsert features whose FID is unset or non-significant (the `--unset-fid` option of *gdal vector edit* can be used to ignore the FID from the source feature), when there is a UNIQUE column that is not the integer primary key.

Examples

Example 1: Write a GeoPackage file

```
$ gdal vector pipeline ... [other commands here] ... ! write out.gpkg --overwrite
```

5.1.5 Multidimensional raster commands

5.1.5.1 gdal mdim

Added in version 3.11.

Synopsis

```
Usage: gdal mdim <SUBCOMMAND> [OPTIONS]
where <SUBCOMMAND> is one of:
  - convert: Convert a multidimensional dataset.
  - info:    Return information on a multidimensional dataset.
  - mosaic:  Build a mosaic, either virtual (VRT) or materialized, from multidimensional␣
↪datasets.

Common Options:
  -h, --help              Display help message and exit
  --json-usage            Display usage as JSON document and exit
  --config <KEY>=<VALUE>  Configuration option [may be repeated]

Options:
  --drivers               Display multidimensional driver list as JSON document
```

Available sub-commands

- *gdal mdim info*
- *gdal mdim convert*
- *gdal mdim mosaic*

Examples

Example 1: Getting information on the file temperatures.nc (with JSON output)

```
$ gdal mdim info temperatures.nc
```

Example 2: Converting file temperatures.nc to Zarr

```
$ gdal mdim convert temperatures.nc temperatures.zarr
```

Example 3: Getting the list of multidimensional drivers (with JSON output)

```
$ gdal mdim --drivers
```

5.1.5.2 gdal mdim info

Added in version 3.11.

Synopsis

```
Usage: gdal mdim info [OPTIONS] <INPUT>

Return information on a multidimensional dataset.

Positional arguments:
  -i, --dataset, --input <INPUT>       Input multidimensional raster dataset [required]

Common Options:
  -h, --help                           Display help message and exit
  --json-usage                         Display usage as JSON document and exit
  --config <KEY>=<VALUE>               Configuration option [may be repeated]

Options:
  --summary                            Report only group and array hierarchy, without␣
↪detailed information on attributes or dimensions.
                                       Mutually exclusive with --detailed
  --detailed                           Most verbose output. Report attribute data types␣
↪and array values.
                                       Mutually exclusive with --summary
  --array <ARRAY>                      Name of the array, used to restrict the output to␣
↪the specified array.
  --limit <LIMIT>                      Number of values in each dimension that is used␣
↪to limit the display of array values.
  --array-option <KEY>=<VALUE>         Option passed to GDALGroup::GetMDArrayNames() to␣
↪filter reported arrays. [may be repeated]
  --stats                              Read and display image statistics.

Advanced Options:
  --oo, --open-option <KEY>=<VALUE>    Open options [may be repeated]
  --if, --input-format <INPUT-FORMAT>  Input formats [may be repeated]
```

Description

gdal mdim info lists various information about a GDAL supported multidimensional dataset, and returns them on the standard output stream when used from the command line, or in the `output` parameter when used from the API.

The following items will be reported (when known) as JSON:

- The format driver used to access the file.
- Hierarchy of groups
- Group attributes
- **Arrays:**
  - Name
  - Dimension name, sizes, indexing variable
  - Data type
  - Attributes
  - SRS
  - Nodata value

- Units
- Statistics (if requested)

The following options are available:

Standard options

--summary

Added in version 3.13.

Report only group and array hierarchy, without detailed information on attributes or dimensions. Mutually exclusive with *--detailed*.

--detailed

Most verbose output. Report attribute data types and array values. Mutually exclusive with *--summary*.

--array <array_name>

Name of the array used to restrict the output to the specified array.

> **Note**
>
> Bash completion for *--array* is possible if the dataset name is specified before.

--limit <number>

Number of values in each dimension that is used to limit the display of array values. By default, unlimited. Only taken into account if used with -detailed.

--array-option <NAME>=<VALUE>

Option passed to *GDALGroup::GetMDArrayNames()* to filter reported arrays. Such option is format specific. Consult driver documentation. This option may be used several times.

> **Note**
>
> Bash completion for *--array-option* is possible if the dataset name is specified before.

--stats

Read and display array statistics. Force computation if no statistics are stored in an array.

Advanced options

--oo, --open-option <NAME>=<VALUE>

Dataset open option (format specific).

May be repeated.

--if, --input-format <format>

Format/driver name to be attempted to open the input file(s). It is generally not necessary to specify it, but it can be used to skip automatic driver detection, when it fails to select the appropriate driver. This option can be repeated several times to specify several candidate drivers. Note that it does not force those drivers to open the dataset. In particular, some drivers have requirements on file extensions.

May be repeated.

Return status code

The program returns status code 0 in case of success, and non-zero in case of error (non-blocking errors emitted as warnings are considered as a successful execution).

5.1.5.3 gdal mdim convert

Added in version 3.11.

Synopsis

```
Usage: gdal mdim convert [OPTIONS] <INPUT> <OUTPUT>

Convert a multidimensional dataset.

Positional arguments:
  -i, --input <INPUT>                                    Input raster or multidimensional␣
↪raster dataset [required]
  -o, --output <OUTPUT>                                  Output multidimensional raster␣
↪dataset (created by algorithm) [required]

Common Options:
  -h, --help                                             Display help message and exit
  --json-usage                                           Display usage as JSON document␣
↪and exit
  --config <KEY>=<VALUE>                                 Configuration option [may be␣
↪repeated]
  -q, --quiet                                            Quiet mode (no progress bar or␣
↪warning message) [not available in pipelines]

Options:
  -f, --of, --format, --output-format <OUTPUT-FORMAT>  Output format
  --co, --creation-option <KEY>=<VALUE>                  Creation option [may be repeated]
  --overwrite                                            Whether overwriting existing␣
↪output dataset is allowed
  --array <ARRAY-SPEC>                                   Select a single array instead of␣
↪converting the whole dataset. [may be repeated]
  --array-option <KEY>=<VALUE>                           Option passed to␣
↪GDALGroup::GetMDArrayNames() to filter arrays. [may be repeated]
  --group <GROUP-SPEC>                                   Select a single group instead of␣
↪converting the whole dataset. [may be repeated]
  --subset <SUBSET-SPEC>                                 Select a subset of the data. [may␣
↪be repeated]
  --scale-axes <SCALEAXES-SPEC>                          Applies a integral scale factor␣
↪to one or several dimensions [may be repeated]
  --strict                                               Turn warnings into failures.

Advanced Options:
  --oo, --open-option <KEY>=<VALUE>                      Open options [may be repeated]
  --if, --input-format <INPUT-FORMAT>                    Input formats [may be repeated]
```

Description

gdal mdim convert can be used to convert multidimensional data between different formats.

The following options are available:

Standard options

-f, --of, --format, --output-format <OUTPUT-FORMAT>

Select the output format. This can be a format that supports multidimensional output (such as *NetCDF: Network Common Data Form*, *Multidimensional VRT*), or a "classic" 2D formats, if only one single 2D array results of the other specified conversion operations. When this option is not specified, the format is guessed when possible from the extension of the destination filename.

--co, --creation-option <KEY>=<VALUE>

Many formats have one or more optional creation options that can be used to control particulars about the file created.

The creation options available vary by format driver, and some simple formats have no creation options at all. A list of options supported for a format can be listed with the *--format* command line option but the documentation for the format is the definitive source of information on driver creation options. See *Raster drivers* format specific documentation for legal creation options for each format.

Array-level creation options may be passed by prefixing them with `ARRAY:`. See *`GDALGroup::CopyFrom()`* for further details regarding such options.

--overwrite

Allow program to overwrite existing target file or dataset. Otherwise, by default, **gdal** errors out if the target file or dataset already exists.

--array <array_spec>

Instead of converting the whole dataset, select one array, and possibly perform operations on it. This option can be specified several times to operate on different arrays.

<array_spec> may be just an array name, potentially using a fully qualified syntax (/group/subgroup/array_name). Or it can be a combination of options with the syntax: name={src_array_name}[,dstname={dst_array_name}][,resample=yes][,transpose=[{axis1},{axis2},...][,view={view_expr}]

The following options are processed in that order:

- `resample=yes` asks for the array to run through *`GDALMDArray::GetResampled()`*.
- **[{axis1},{axis2},...] is the argument of *`GDALMDArray::Transpose()`*.**
  For example, transpose=[1,0] switches the axis order of a 2D array. See *Example 6*.
- {view_expr} is the value of the *viewExpr* argument of *`GDALMDArray::GetView()`*. See *Example 5*.

When specifying a view_expr that performs a slicing or subsetting on a dimension, the equivalent operation will be applied to the corresponding indexing variable.

--array-option <NAME>=<VALUE>

Option passed to *`GDALGroup::GetMDArrayNames()`* to filter reported arrays. Such option is format specific. Consult driver documentation. This option may be used several times.

--group <group_spec>

Instead of converting the whole dataset, select one group, and possibly perform operations on it. This option can be specified several times to operate on different groups. If only one group is specified, its content will be copied directly to the target root group. If several ones are specified, they are copied under the target root group

<group_spec> may be just a group name, potentially using a fully qualified syntax (/group/subgroup/subsubgroup_name). Or it can be a combination of options with the syntax: `name={src_group_name}[,dstname={dst_group_name}][,recursive=no]`

--subset <subset_spec>

Performs a subsetting (trimming or slicing) operation along a dimension, provided that it is indexed by a 1D variable of numeric or string data type, and whose values are monotonically sorted. <subset_spec> follows exactly the OGC WCS 2.0 KVP encoding for subsetting.

That is `dim_name(min_val,max_val)` or `dim_name(sliced_val)` The first syntax will subset the dimension `dim_name` to values in the [min_val,max_val] range. The second syntax will slice the dimension dim_name to value sliced_val (and this dimension will be removed from the arrays that reference to it)

Beware that dimension name is case sensitive.

Several subsetting operations along different dimensions can be specified by repeating the option.

Using --subset is incompatible with specifying a *view* option in --array.

See *Example 2* or *Example 3*.

--scale-axes <scaleaxes_spec>

Applies a integral scale factor to one or several dimensions, that is extract 1 value every N values (without resampling).

<scaleaxes_spec> follows exactly the syntax of the KVP encoding of the SCALEAXES parameter of OGC WCS 2.0 Scaling Extension, but limited to integer scale factors.

That is `<dim1_name>(<scale_factor>)`.

Several scaling operations along different dimensions can be specified by repeating the option.

Using --scale-axes is incompatible with specifying a *view* option in --array.

See *Example 4*.

--strict

By default, some failures during the translation are tolerated, such as not being able to write group attributes. When setting this option, such failures will cause the process to fail.

Advanced options

--oo, --open-option <NAME>=<VALUE>

Dataset open option (format specific).

May be repeated.

--if, --input-format <format>

Format/driver name to be attempted to open the input file(s). It is generally not necessary to specify it, but it can be used to skip automatic driver detection, when it fails to select the appropriate driver. This option can be repeated several times to specify several candidate drivers. Note that it does not force those drivers to open the dataset. In particular, some drivers have requirements on file extensions.

May be repeated.

Return status code

The program returns status code 0 in case of success, and non-zero in case of error (non-blocking errors emitted as warnings are considered as a successful execution).

Examples

Example 1: Convert a netCDF file to a multidimensional VRT file

```
gdal mdim convert in.nc out.vrt
```

Example 2: Extract a 2D slice of a time,Y,X array

```
gdal mdim convert in.nc out.tif --subset "time(\"2010-01-01\")" --array temperature
```

Example 3: Extract a a 3D chunk from a time-indexed GRIB file into a multiband GeoTIFF.

```
gdal mdim convert /vsicurl/https://tgftp.nws.noaa.gov/SL.us008001/ST.opnl/DF.gr2/DC.ndfd/
↪AR.conus/VP.001-003/ds.qpf.bin tst.tif --subset "TIME(1763164800,1763251200)" --array␣
↪QPF_0-SFC --co COMPRESS=DEFLATE
```

Example 4: Subsample along x and y axis

```
gdal mdim convert in.nc out.nc --scale-axes "x(2),y(2)"
```

Example 5: Reorder the values of an array

Reorder the values of the time,Y,X array along the Y axis from top-to-bottom to bottom-to-top (or the reverse)

```
gdal mdim convert in.nc out.nc --array "name=temperature,view=[:,::-1,:]"
```

Example 6: Transpose an array that has X,Y,time dimension order to time,Y,X

```
gdal mdim convert in.nc out.nc --array "name=temperature,transpose=[2,1,0]"
```

5.1.5.4 gdal mdim mosaic

Added in version 3.12.

Synopsis

```
Usage: gdal mdim mosaic [OPTIONS] <INPUT>... <OUTPUT>

Build a mosaic, either virtual (VRT) or materialized, from multidimensional datasets.

Positional arguments:
  -i, --input <INPUT>                                    Input multidimensional raster␣
↪datasets [1.. values] [required]
  -o, --output <OUTPUT>                                  Output multidimensional raster␣
↪dataset (created by algorithm) [required]

Common Options:
  -h, --help                                             Display help message and exit
  --json-usage                                           Display usage as JSON document␣
```

  --if, --input-format <INPUT-FORMAT>                   Input formats [may be repeated]
```

Description

gdal mdim mosaic builds a mosaic of multidimensional array(s), from a list of input GDAL multidimensional datasets, that can be either a virtual mosaic in the *Multidimensional VRT (Virtual Dataset)* format, or in a more conventional multidimensional format such as *NetCDF: Network Common Data Form* or *Zarr*.

Wildcards '*', '?' or '[']of *VSIGlob()* can be used for input dataset names, even on files located on network file systems such as /vsis3/, /vsigs/, /vsiaz/, etc. Alternatively if an input dataset name is prefixed by the @ character, it will be assumed to contain the list of actual dataset names (one per line) to use as input datasets.

To create a mosaic from an array, certain structural constraints apply to all contributing arrays from the input datasets:

- All contributing arrays must have the same array name and path (e.g. "/measurements/pressure")
- They must have the same data type and nodata value
- They must share the same number of dimensions, in the same order, and with the same names.
- each dimension of the array must have an associated one-dimensional numeric indexing variable.

A typical use case is when a multidimensional array is sliced into several files, and it is desired to reconstruct the full array.

The program can support mosaicing along several axes.

There might be "holes" among the source datasets along the mosaiced dimensions, and possibly overlaps (but only when regularly spacing along a mosaiced dimension). Holes are filled with the nodata value, if defined in the source arrays, or zero-initialized otherwise. In case of overlap, the order of the input list is used to determine priority. Files that are listed at the end are the ones from which the content will be fetched.

Different typical use cases that can be addressed by this program are:

- a 3D array is sliced along a single dimension (for example a temporal one) into several files with each slice having a sample along that dimension. In that use case, the timestamps of the slices do not need to be regularly spaced.
- a 2D array is chunked/tiled along X and Y dimensions, with a regular spacing along those X and Y dimensions, and where the coordinate values are aligned on the same grid among chunks.

By default, a target array is created for each array with two or more dimensions. This behavior can be restricted to specific arrays using the *--array* option.

The following options are available:

Standard options

-i, --input <INPUT>

Input multidimensional dataset names. Required.

Wildcards '*', '?' or '['] of *VSIGlob()* can be used for input dataset names, even on files located on network file systems such as /vsis3/, /vsigs/, /vsiaz/, etc. Alternatively if a input dataset name is prefixed by the @ character, it will be assumed to contain the list of actual dataset names (one per line) to use as input datasets.

-o, --output <OUTPUT>

Output multidimensional dataset name. Required.

-f, --of, --format, --output-format <OUTPUT-FORMAT>

Select the output format. This can be a format that supports multidimensional output (such as *NetCDF: Network Common Data Form*, *Multidimensional VRT*). When this option is not specified, the format is guessed when possible from the extension of the destination filename.

--co, --creation-option <KEY>=<VALUE>

Many formats have one or more optional creation options that can be used to control particulars about the file created.

The creation options available vary by format driver, and some simple formats have no creation options at all. A list of options supported for a format can be listed with the *--format* command line option but the documentation for the format is the definitive source of information on driver creation options. See *Raster drivers* format specific documentation for legal creation options for each format.

Array-level creation options may be passed by prefixing them with `ARRAY:`. See *GDALGroup::CopyFrom()* for further details regarding such options.

--overwrite

Allow program to overwrite existing target file or dataset. Otherwise, by default, **gdal** errors out if the target file or dataset already exists.

--array <ARRAYS>

Name or full path of one or several arrays to mosaic. If not specified, a target array is created for each array with two or more dimensions.

Advanced options

--oo, --open-option <NAME>=<VALUE>

Dataset open option (format specific).

May be repeated.

--if, --input-format <format>

Format/driver name to be attempted to open the input file(s). It is generally not necessary to specify it, but it can be used to skip automatic driver detection, when it fails to select the appropriate driver. This option can be repeated several times to specify several candidate drivers. Note that it does not force those drivers to open the dataset. In particular, some drivers have requirements on file extensions.

May be repeated.

Return status code

The program returns status code 0 in case of success, and non-zero in case of error (non-blocking errors emitted as warnings are considered as a successful execution).

Examples

Example 1: Mosaic together all netCDF files starting with slice that are slices of a 3D array

```
gdal mdim mosaic slice*.nc out.vrt
```

5.1.6 Dataset management commands

5.1.6.1 gdal dataset

Added in version 3.12.

gdal dataset can perform various operations on data files, depending on the chosen operation. This includes identifying data types and deleting, renaming or copying the files.

Synopsis

```
Usage: gdal dataset <SUBCOMMAND> [OPTIONS]
where <SUBCOMMAND> is one of:
  - check:    Check whether there are errors when reading the content of a dataset.
  - copy:     Copy files of a dataset. (alias: cp)
  - delete:   Delete dataset(s). (alias: rm, remove)
  - identify: Identify driver opening dataset(s).
  - rename:   Rename files of a dataset. (alias: ren, mv)

Common Options:
  -h, --help              Display help message and exit
  --json-usage            Display usage as JSON document and exit
  --config <KEY>=<VALUE>  Configuration option [may be repeated]
```

Available sub-commands

- *gdal dataset identify*: Identify driver opening dataset(s)
- *gdal dataset check*: Check whether there are errors when reading the content of a dataset.
- *gdal dataset copy*: Copy files of a dataset.
- *gdal dataset rename*: Rename files of a dataset.
- *gdal dataset delete*: Delete dataset(s)

5.1.6.2 gdal dataset identify

Added in version 3.12.

gdal dataset identify reports the name of drivers that can open one or several dataset(s).

Synopsis

```
Usage: gdal dataset identify [OPTIONS] <FILENAME>

Identify driver opening dataset(s).

Positional arguments:
  --input, --filename <FILENAME>                      File or directory name [may be␣
↪repeated] [required]

Common Options:
  -h, --help                                          Display help message and exit
  --json-usage                                        Display usage as JSON document␣
↪and exit
  --config <KEY>=<VALUE>                              Configuration option [may be␣
↪repeated]
  -q, --quiet                                         Quiet mode (no progress bar or␣
↪warning message) [not available in pipelines]

Options:
  -o, --output <OUTPUT>                               Output vector dataset (created by␣
↪algorithm)
  -f, --of, --format, --output-format <OUTPUT-FORMAT>  Output format
  --co, --creation-option <KEY>=<VALUE>               Creation option [may be repeated]
  --lco, --layer-creation-option <KEY>=<VALUE>        Layer creation option [may be␣
↪repeated]
  -l, --output-layer <OUTPUT-LAYER>                   Output layer name
  --overwrite                                         Whether overwriting existing␣
↪output dataset is allowed
  -r, --recursive                                     Recursively scan files/folders␣
↪for datasets
  --force-recursive                                   Recursively scan folders for␣
↪datasets, forcing recursion in folders recognized as valid formats
  --detailed                                          Most detailed output. Reports the␣
↪presence of georeferencing, if a GeoTIFF file is cloud optimized, etc.
  --report-failures                                   Report failures if file type is␣
↪unidentified
```

Options

--filename <FILENAME>

Any file name or directory name. Required. May be repeated

-o, --output <OUTPUT>

Added in version 3.13.

Output vector dataset that will have at a minimum fields `filename` and `driver`, and if *--detailed* is specified, also `layout` (whose value can be for example `COG`), `file_list` (side-car files), `has_crs`, `has_geotransform` and `has_overview`.

When this argument is not specified, the result report is emitted to the standard output stream, either as JSON or text (depending on *--output-format*), for command line execution, or in the `output-string` argument when used from the API.

Note that this is not a positional argument, so the `-o` or `--output` switch must be explicitly used before specifying

the name.

-f, --of, --format, --output-format `json|text|<OTHER-VECTOR-FORMAT>`

Which output format to use. Default is JSON, or text when invoked from command line.

Since GDAL 3.13, other GDAL vector formats with creation capabilities can be used, in which case *--output* must be specified.

-r, --recursive

Recursively scan files/folders for datasets.

--force-recursive

Recursively scan folders for datasets, forcing recursion in folders recognized as valid formats.

--detailed

Added in version 3.13.

Increases the level of details in the output. Reports the presence of georeferencing, if a GeoTIFF file is cloud optimized, etc.

--report-failures

Report failures if file type is unidentified.

Return status code

The program returns status code 0 in case of success, and non-zero in case of error (non-blocking errors emitted as warnings are considered as a successful execution).

Examples

Example 1: Identifying a single file

```
$ gdal dataset identify NE1_50M_SR_W.tif

NE1_50M_SR_W.tif: GTiff
```

Example 2: Identifying a single file with JSON output

```
$ gdal dataset identify --of=JSON NE1_50M_SR_W.tif
```

```
[
   {
     "name": "NE1_50M_SR_W.tif",
     "driver": "GTiff"
   }
]
```

Example 3: Recursive mode will scan subfolders and report the data format

```
$ gdal dataset identify -r 50m_raster/

NE1_50M_SR_W/ne1_50m.jpg: JPEG
NE1_50M_SR_W/ne1_50m.png: PNG
NE1_50M_SR_W/ne1_50m_20pct.tif: GTiff
```

(continues on next page)

(continued from previous page)

```
NE1_50M_SR_W/ne1_50m_band1.tif: GTiff
NE1_50M_SR_W/ne1_50m_print.png: PNG
NE1_50M_SR_W/NE1_50M_SR_W.aux: HFA
NE1_50M_SR_W/NE1_50M_SR_W.tif: GTiff
NE1_50M_SR_W/ne1_50m_sub.tif: GTiff
NE1_50M_SR_W/ne1_50m_sub2.tif: GTiff
```

Example 4: Recursively scans subfolders and reports detailed information into a CSV file

```
$ gdal dataset identify --output out.csv --detailed -r 50m_raster/
```

Example 5: Check if a GeoTIFF file is cloud optimized using --detailed

The following returns driver, and image layout details: `GTiff, layout=COG, has CRS, has geotransform, has overview(s)`

```
$ gdal dataset identify /vsicurl/https://sentinel-cogs.s3.us-west-2.amazonaws.
↪com/sentinel-s2-l2a-cogs/36/Q/WD/2020/7/S2A_36QWD_20200701_0_L2A/TCI.tif --
↪detailed
```

5.1.6.3 `gdal dataset check`

Added in version 3.13.

`gdal dataset check` check whether there are errors when reading the content of a dataset and return 1 as the program exit code (or in the `return-code` output parameter of the algorithm) if that happens, or 0 when no errors are detected.

> **Warning**
>
> Most drivers or data formats do not have a built-in integrity mechanism. Thus a successful run of that program does not necessarily mean that the dataset is identical to the state it had just after being generated. The checks performed are generally sufficient to detect whether the dataset is truncated compared to its expected size, but this is not even necessarily guaranteed for some formats (for example the CSV driver may not be able to detect truncation).

Synopsis

```
Usage: gdal dataset check [OPTIONS] <INPUT>

Check whether there are errors when reading the content of a dataset.

Positional arguments:
  -i, --input <INPUT>                 Input raster, vector or multidimensional raster␣
↪dataset [required]

Common Options:
  -h, --help                          Display help message and exit
  --json-usage                        Display usage as JSON document and exit
  --config <KEY>=<VALUE>              Configuration option [may be repeated]
  -q, --quiet                         Quiet mode (no progress bar or warning message)␣
↪[not available in pipelines]
```

(continues on next page)

(continued from previous page)

```
Advanced Options:
  --oo, --open-option <KEY>=<VALUE>    Open options [may be repeated]
  --if, --input-format <INPUT-FORMAT>  Input formats [may be repeated]
```

Options

--input <FILENAME>

Input vector, raster or multidimensional dataset. Required.

Return status code

The program returns status code 0 in case of success, and non-zero in case of error (non-blocking errors emitted as warnings are considered as a successful execution).

Examples

Example 1: Check whether there are errors when reading a dataset

```
$ gdal dataset check NE1_50M_SR_W.tif
```

5.1.6.4 gdal dataset copy

Added in version 3.12.

gdal dataset copy creates a copy of the dataset file(s), including potential side-car/associated files.

Synopsis

```
Usage: gdal dataset copy [OPTIONS] <SOURCE> <DESTINATION>

Copy files of a dataset.

Positional arguments:
  --source <SOURCE>            Source dataset name [required]
  --destination <DESTINATION>  Destination dataset name [required]

Common Options:
  -h, --help                   Display help message and exit
  --json-usage                 Display usage as JSON document and exit
  --config <KEY>=<VALUE>       Configuration option [may be repeated]

Options:
  --overwrite                  Whether overwriting existing output dataset is allowed

Advanced Options:
  -f, --format <FORMAT>        Dataset format
```

Options

--source <FILENAME>

Source file name or directory name. Required.

--destination <FILENAME>

Destination file name or directory name. Required.

-f, ---format <FORMAT>

Dataset format. Helps if automatic detection does not work.

--overwrite

Allow program to overwrite existing target file or dataset. Otherwise, by default, **gdal** errors out if the target file or dataset already exists.

Return status code

The program returns status code 0 in case of success, and non-zero in case of error (non-blocking errors emitted as warnings are considered as a successful execution).

Examples

Example 1: Copy a dataset

```
$ gdal dataset copy source.tif destination.tif
```

5.1.6.5 gdal dataset rename

Added in version 3.12.

gdal dataset rename rename the dataset file(s), including potential side-car/associated files.

Synopsis

```
Usage: gdal dataset rename [OPTIONS] <SOURCE> <DESTINATION>

Rename files of a dataset.

Positional arguments:
  --source <SOURCE>            Source dataset name [required]
  --destination <DESTINATION>  Destination dataset name [required]

Common Options:
  -h, --help                   Display help message and exit
  --json-usage                 Display usage as JSON document and exit
  --config <KEY>=<VALUE>       Configuration option [may be repeated]

Options:
  --overwrite                  Whether overwriting existing output dataset is allowed

Advanced Options:
  -f, --format <FORMAT>        Dataset format
```

Options

--source <FILENAME>

Source file name or directory name. Required.

--destination <FILENAME>

Destination file name or directory name. Required.

-f, ---format <FORMAT>

Dataset format. Overrides the automatic format detection.

--overwrite

Allow program to overwrite existing target file or dataset. Otherwise, by default, **gdal** errors out if the target file or dataset already exists.

Return status code

The program returns status code 0 in case of success, and non-zero in case of error (non-blocking errors emitted as warnings are considered as a successful execution).

Examples

Example 1: Rename a dataset

```
$ gdal dataset rename old_name.tif new_name.tif
```

5.1.6.6 gdal dataset delete

Added in version 3.12.

gdal dataset delete delete dataset(s), including potential side-car/associated files.

Synopsis

```
Usage: gdal dataset delete [OPTIONS] <FILENAME>

Delete dataset(s).

Positional arguments:
  --filename <FILENAME>   File or directory name [may be repeated] [required]

Common Options:
  -h, --help              Display help message and exit
  --json-usage            Display usage as JSON document and exit
  --config <KEY>=<VALUE>  Configuration option [may be repeated]

Advanced Options:
  -f, --format <FORMAT>   Dataset format
```

Options

--filename <FILENAME>

Any file name or directory name. Required. May be repeated

-f, ---format <FORMAT>

Dataset format. Helps if automatic detection does not work.

Return status code

The program returns status code 0 in case of success, and non-zero in case of error (non-blocking errors emitted as warnings are considered as a successful execution).

Examples

Example 1: Delete a dataset

```
$ gdal dataset delete NE1_50M_SR_W.tif
```

5.1.7 Virtual System Interface (VSI) commands

5.1.7.1 gdal vsi

Added in version 3.11.

The subcommands of **gdal vsi** allow manipulation of files located on the *GDAL Virtual File Systems (compressed, network hosted, etc...): /vsimem, /vsizip, /vsitar, /vsicurl, ...*.

Synopsis

```
Usage: gdal vsi <SUBCOMMAND> [OPTIONS]
where <SUBCOMMAND> is one of:
  - copy:   Copy files located on GDAL Virtual System Interface (VSI). (alias: cp)
  - delete: Delete files located on GDAL Virtual System Interface (VSI). (alias: rm,␣
↪rmdir, del)
  - list:   List files of one of the GDAL Virtual System Interface (VSI). (alias: ls)
  - move:   Move/rename a file/directory located on GDAL Virtual System Interface (VSI).␣
↪(alias: mv, ren, rename)
  - sozip:  Seek-optimized ZIP (SOZIP) commands.
  - sync:   Synchronize source and target file/directory located on GDAL Virtual System␣
↪Interface (VSI).

Common Options:
  -h, --help              Display help message and exit
  --json-usage            Display usage as JSON document and exit
  --config <KEY>=<VALUE>  Configuration option [may be repeated]
```

Available sub-commands

- *gdal vsi copy*
- *gdal vsi delete*
- *gdal vsi list*
- *gdal vsi move*
- *gdal vsi sync*
- *gdal vsi sozip*

Examples

Example 1: Listing recursively files in /vsis3/bucket with details

```
$ gdal vsi list -lR /vsis3/bucket
```

5.1.7.2 gdal vsi copy

Added in version 3.11.

Synopsis

```
Usage: gdal vsi copy [OPTIONS] <SOURCE> <DESTINATION>

Copy files located on GDAL Virtual System Interface (VSI).

Positional arguments:
  --source <SOURCE>            Source file or directory name [required]
  --destination <DESTINATION>  Destination file or directory name [required]

Common Options:
  -h, --help                   Display help message and exit
  --json-usage                 Display usage as JSON document and exit
  --config <KEY>=<VALUE>       Configuration option [may be repeated]
  -q, --quiet                  Quiet mode (no progress bar or warning message) [not␣
↪available in pipelines]

Options:
  -r, --recursive              Copy subdirectories recursively
  --skip-errors                Skip errors
```

Description

gdal vsi copy copy files and directories located on *GDAL Virtual File Systems (compressed, network hosted, etc...): /vsimem, /vsizip, /vsitar, /vsicurl, ...*.

It can copy files and directories between different virtual file systems.

This is the equivalent of the UNIX `cp` command, and `gdal vsi cp` is an alias for `gdal vsi copy`.

Options

-r, --recursive

Copy directories recursively.

--skip-errors

Skip errors that occur while while copying.

Return status code

The program returns status code 0 in case of success, and non-zero in case of error (non-blocking errors emitted as warnings are considered as a successful execution).

Examples

Example 1: Copy recursively files from /vsis3/bucket/my_dir to local directory, creating a my_dir directory if it does not exist.

```
$ gdal vsi copy -r /vsis3/bucket/my_dir .
```

Example 2: Copy recursively files from /vsis3/bucket/my_dir to local directory, without creating a my_dir directory, without progress bar

```
$ gdal vsi copy --quiet -r /vsis3/bucket/my_dir/* .
```

5.1.7.3 gdal vsi delete

Added in version 3.11.

Synopsis

```
Usage: gdal vsi delete [OPTIONS] <FILENAME>

Delete files located on GDAL Virtual System Interface (VSI).

Positional arguments:
  --filename <FILENAME>   File or directory name to delete [required]

Common Options:
  -h, --help              Display help message and exit
  --json-usage            Display usage as JSON document and exit
  --config <KEY>=<VALUE>  Configuration option [may be repeated]

Options:
  -r, -R, --recursive     Delete directories recursively
```

Description

gdal vsi delete delete files and directories located on *GDAL Virtual File Systems (compressed, network hosted, etc...): /vsimem, /vsizip, /vsitar, /vsicurl, ...*.

This is the equivalent of the UNIX `rm` command, and `gdal vsi rm` is an alias for `gdal vsi delete`.

> **Warning**
>
> Be careful. This command cannot be undone. It can also act on the "real" file system.

Options

-r, -R, --recursive

Delete directories recursively.

Return status code

The program returns status code 0 in case of success, and non-zero in case of error (non-blocking errors emitted as warnings are considered as a successful execution).

Examples

Example 1: Delete recursively files from /vsis3/bucket/my_dir

```
$ gdal vsi delete -r /vsis3/bucket/my_dir
```

5.1.7.4 gdal vsi list

Added in version 3.11.

Synopsis

```
Usage: gdal vsi list [OPTIONS] <FILENAME>

List files of one of the GDAL Virtual System Interface (VSI).

Positional arguments:
  --filename <FILENAME>                                File or directory name [required]

Common Options:
  -h, --help                                           Display help message and exit
  --json-usage                                         Display usage as JSON document␣
↪and exit
  --config <KEY>=<VALUE>                               Configuration option [may be␣
↪repeated]

Options:
  -f, --of, --format, --output-format <OUTPUT-FORMAT>  Output format. OUTPUT-
↪FORMAT=json|text
  -l, --long, --long-listing                           Use a long listing format
  -R, --recursive                                      List subdirectories recursively
  --depth <DEPTH>                                      Maximum depth in recursive mode
  --abs, --absolute-path                               Display absolute path
  --tree                                               Use a hierarchical presentation␣
↪for JSON output
```

Description

gdal vsi list list files of *GDAL Virtual File Systems (compressed, network hosted, etc...): /vsimem, /vsizip, /vsitar, /vsicurl, ...*.

This is the equivalent of the UNIX `ls` command, and `gdal vsi ls` is an alias for `gdal vsi list`.

By default, it outputs file names, at the immediate level, without details, and in JSON format.

Options

--filename <FILENAME>

Any file name or directory name, of one of the GDAL Virtual file systems. Required.

-f, --of, --format, --output-format `json|text`

Which output format to use. Default is JSON, and starting with GDAL 3.12, text when invoked from command line.

-l, --long, --long-listing

Use a long listing format, adding permissions, file size and last modification date.

-R, --recursive

List subdirectories recursively. By default the depth is unlimited, but it can be reduced with *--depth*.

--depth <DEPTH>

Maximum depth in recursive mode. 1 corresponds to no recursion, 2 to the immediate subdirectories, etc.

--abs, --absolute-path

Whether to report file names as absolute paths. By default, they are relative to the input file name.

--tree

Use a hierarchical presentation for JSON output, instead of a flat list. Only valid when *--output-format* is set to `json` (or let at its default value).

Return status code

The program returns status code 0 in case of success, and non-zero in case of error (non-blocking errors emitted as warnings are considered as a successful execution).

Examples

Example 1: Listing recursively files in /vsis3/bucket with details

```
$ gdal vsi list -lR /vsis3/bucket
```

5.1.7.5 gdal vsi move

Added in version 3.11.

Synopsis

```
Usage: gdal vsi move [OPTIONS] <SOURCE> <DESTINATION>

Move/rename a file/directory located on GDAL Virtual System Interface (VSI).

Positional arguments:
  --source <SOURCE>            Source file or directory name [required]
  --destination <DESTINATION>  Destination file or directory name [required]

Common Options:
  -h, --help                   Display help message and exit
  --json-usage                 Display usage as JSON document and exit
  --config <KEY>=<VALUE>       Configuration option [may be repeated]
```

(continues on next page)

(continued from previous page)

```
  -q, --quiet                  Quiet mode (no progress bar or warning message) [not␣
↪available in pipelines]
```

Description

gdal vsi move move files and directories located on *GDAL Virtual File Systems (compressed, network hosted, etc...): /vsimem, /vsizip, /vsitar, /vsicurl, ...*.

If the destination path is an existing directory, the file will be moved to it.

It can move files and directories between different virtual file systems, but this will involve copying and deletion.

Note that for cloud object storage, moving/renaming a directory may involve renaming all files it contains recursively, and is thus not an atomic operation (and could be slow and expensive on directories with many files!)

This is implemented by *VSIMove()*.

This is an analog of the UNIX `mv` command, and `gdal vsi mv` is an alias for `gdal vsi move`.

Return status code

The program returns status code 0 in case of success, and non-zero in case of error (non-blocking errors emitted as warnings are considered as a successful execution).

Examples

Example 1: Rename a file within the same virtual file system

```
$ gdal vsi move /vsis3/bucket/my.tif /vsis3/bucket/new_name.tif
```

Example 2: Move a file into another directory within the same virtual file system

```
$ gdal vsi move /vsis3/bucket/my.tif /vsis3/bucket/existing_subdir
```

Example 3: Move a directory between two different virtual file systems

```
$ gdal vsi move /vsis3/bucket/my_directory /vsigs/bucket/
```

5.1.7.6 gdal vsi sync

Added in version 3.11.

Synopsis

```
Usage: gdal vsi sync [OPTIONS] <SOURCE> <DESTINATION>

Synchronize source and target file/directory located on GDAL Virtual System Interface␣
↪(VSI).

Positional arguments:
  --source <SOURCE>                Source file or directory name [required]
  --destination <DESTINATION>      Destination file or directory name [required]
```

(continues on next page)

(continued from previous page)

```
Common Options:
  -h, --help                        Display help message and exit
  --json-usage                      Display usage as JSON document and exit
  --config <KEY>=<VALUE>            Configuration option [may be repeated]
  -q, --quiet                       Quiet mode (no progress bar or warning message) [not␣
↪available in pipelines]

Options:
  -r, --recursive                   Synchronize recursively
  --strategy <STRATEGY>             Synchronization strategy.␣
↪STRATEGY=timestamp|ETag|overwrite (default: timestamp)
  -j, --num-threads <NUM-THREADS>   Number of jobs (or ALL_CPUS)
```

Description

gdal vsi sync synchronize files and directories located on *GDAL Virtual File Systems (compressed, network hosted, etc...): /vsimem, /vsizip, /vsitar, /vsicurl, ...*.

This is an analog to the UNIX **rsync** command. In the current implementation, **rsync** would be more efficient for local file copying, but **gdal vsi sync** main interest is when the source or target is a remote file system like /vsis3/ or /vsigs/, in which case it can take into account the timestamps of the files (or optionally the ETag/MD5Sum) to avoid unneeded copy operations.

This is implemented efficiently for:

- local filesystem <--> remote filesystem.
- remote filesystem <--> remote filesystem, where the source and target remote filesystems are the same and one of /vsis3/, /vsigs/ or /vsiaz/. Or when the target is /vsiaz/ and the source is /vsis3/, /vsigs/, /vsiadls/ or /vsicurl/

Similarly to **rsync** behavior, if the source filename ends with a slash, it means that the content of the directory must be copied, but not the directory name. For example, assuming `/home/even/foo` contains a file `bar`, `gdal vsi sync -r /home/even/foo/ /mnt/media` will create a `/mnt/media/bar` file. Whereas `gdal vsi sync -r /home/even/foo /mnt/media` will create a `/mnt/media/foo` directory which contains a `bar` file.

This is implemented by *VSISync()*.

Options

-r, --recursive

Synchronize recursively.

--strategy `timestamp|ETag|overwrite`

Determines which criterion is used to determine if a target file must be replaced when it already exists and has the same file size as the source. Only applies for a source or target being a network filesystem.

The default is `timestamp` (similarly to how **aws s3 sync** works). For an upload operation, a remote file is replaced if it has a different size or if it is older than the source. For a download operation, a local file is replaced if it has a different size or if it is newer than the remote file.

The `ETag` strategy assumes that the ETag metadata of the remote file is the MD5Sum of the file content, which is only true in the case of /vsis3/ for files not using KMS server side encryption and uploaded in a single PUT operation (so smaller than 50 MB given the default used by GDAL). Only to be used for /vsis3/, /vsigs/ or other filesystems using a MD5Sum as ETAG.

The `overwrite` strategy will always overwrite the target file with the source one.

-j, --num-threads <value>

Number of jobs to run at once

Return status code

The program returns status code 0 in case of success, and non-zero in case of error (non-blocking errors emitted as warnings are considered as a successful execution).

Examples

Example 1: Synchronize a local directory onto a S3 bucket

```
$ gdal vsi sync -r my_directory/ /vsis3/bucket/my_directory
```

5.1.7.7 gdal vsi sozip

Added in version 3.11.

Description

The **gdal vsi sozip** utility can be used to:

- create a *SOZip (Seek-Optimized ZIP)* file
- append files to an existing ZIP/SOZip file
- list the contents of a ZIP/SOZip file
- validate a SOZip file
- convert an existing Zip file into a SOZip optimized one

Synopsis

```
Usage: gdal vsi sozip <SUBCOMMAND> [OPTIONS]
where <SUBCOMMAND> is one of:
  - create:   Create a Seek-optimized ZIP (SOZIP) file.
  - list:     List content of a ZIP file, with SOZIP related information.
  - optimize: Create a Seek-optimized ZIP (SOZIP) file from a regular ZIP file.
  - validate: Validate a ZIP file, possibly using SOZIP optimization.

Common Options:
  -h, --help              Display help message and exit
  --json-usage            Display usage as JSON document and exit
  --config <KEY>=<VALUE>  Configuration option [may be repeated]
```

"gdal vsi sozip create"

Description

Adds one or several files to a new or existing zip file.

Synopsis

```
Usage: gdal vsi sozip create [OPTIONS] <INPUT> <OUTPUT>

Create a Seek-optimized ZIP (SOZIP) file.

Positional arguments:
  -i, --input <INPUT>                                        Input filenames [may be␣
↪repeated] [required]
  -o, --output <OUTPUT>                                      Output ZIP filename␣
↪[required]

Common Options:
  -h, --help                                                 Display help message and␣
↪exit
  --json-usage                                               Display usage as JSON␣
↪document and exit
  --config <KEY>=<VALUE>                                     Configuration option [may␣
↪be repeated]
  -q, --quiet                                                Quiet mode (no progress␣
↪bar or warning message) [not available in pipelines]

Options:
  --overwrite                                                Whether overwriting␣
↪existing output dataset is allowed
  -r, --recursive                                            Travels the directory␣
↪structure of the specified directories recursively
  -j, --junk-paths, --no-paths                               Store just the name of a␣
↪saved file, and do not store directory names
  --enable-sozip <ENABLE-SOZIP>                              Whether to automatically/
↪systematically/never apply the SOZIP optimization. ENABLE-SOZIP=auto|yes|no (default:␣
↪auto)
  --sozip-chunk-size <value in bytes or with K/M suffix>       Chunk size for a seek-
↪optimized file (default: 32768)
  --sozip-min-file-size <value in bytes or with K/M/G suffix>  Minimum file size to␣
↪decide if a file should be seek-optimized (default: 1 MB)
  --content-type <CONTENT-TYPE>                              Store the Content-Type of␣
↪the file being added.
```

Options

-i, --input <INPUT>

Input filenames. Required. Several file names or directory names accepted.

-o, --output <OUTPUT>

Output ZIP filename. Required. Must have a `.zip` extension

--overwrite

Whether overwriting existing output is allowed.

-r, --recursive

Travels the directory structure of the specified directories recursively.

-j, --junk-paths, --no-paths

Store just the name of a saved file (junk the path), and do not store directory names. By default, sozip will store the full path (relative to the current directory).

--enable-sozip auto|yes|no

In auto mode, a file is seek-optimized only if its size is above the value of *--sozip-min-file-size*. In yes mode, all input files will be seek-optimized. In no mode, no input files will be seek-optimized.

--sozip-chunk-size <value>

Chunk size for a seek-optimized file. Defaults to 32768 bytes. The value is specified in bytes, or K and M suffix (optionally preceded by a space) can be respectively used to specify a value in kilo-bytes or mega-bytes.

--sozip-min-file-size <value>

Minimum file size to decide if a file should be seek-optimized, in --enable-sozip=auto mode. Defaults to 1 MB byte. The value is specified in bytes, or K, M or G suffix (optionally preceded by a space) can be respectively used to specify a value in kilo-bytes, mega-bytes or giga-bytes.

--content-type <value>

Store the Content-Type for the file being added as a key-value pair in the extra field extension 'KV' (0x564b) dedicated to storing key-value pair metadata

-q, --quiet

Do not output any informative message (only errors).

Multithreading

The *GDAL_NUM_THREADS* configuration option can be set to ALL_CPUS or a integer value to specify the number of threads to use for SOZip-compressed files. Defaults to ALL_CPUS.

Examples

Example 1: Create a, potentially seek-optimized, ZIP file with the content of my.gpkg

```
gdal vsi sozip create my.gpkg my.gpkg.zip
```

Example 2: Create a, potentially seek-optimized, ZIP file from the content of a source directory:

```
gdal vsi sozip create -r source_dir/ my.gpkg.zip
```

"gdal vsi sozip optimize"

Description

Create a new zip file from the content of an existing one, possibly applying SOZip optimization when relevant.

Synopsis

```
Usage: gdal vsi sozip optimize [OPTIONS] <INPUT> <OUTPUT>

Create a Seek-optimized ZIP (SOZIP) file from a regular ZIP file.

Positional arguments:
  -i, --input <INPUT>                                        Input ZIP filename␣
```

(continues on next page)

(continued from previous page)

```
↪[required]
  -o, --output <OUTPUT>                                        Output ZIP filename␣
↪[required]

Common Options:
  -h, --help                                                   Display help message and␣
↪exit
  --json-usage                                                 Display usage as JSON␣
↪document and exit
  --config <KEY>=<VALUE>                                       Configuration option [may␣
↪be repeated]
  -q, --quiet                                                  Quiet mode (no progress␣
↪bar or warning message) [not available in pipelines]

Options:
  --overwrite                                                  Whether overwriting␣
↪existing output dataset is allowed
  --enable-sozip <ENABLE-SOZIP>                                Whether to automatically/
↪systematically/never apply the SOZIP optimization. ENABLE-SOZIP=auto|yes|no (default:␣
↪auto)
  --sozip-chunk-size <value in bytes or with K/M suffix>       Chunk size for a seek-
↪optimized file (default: 32768)
  --sozip-min-file-size <value in bytes or with K/M/G suffix>  Minimum file size to␣
↪decide if a file should be seek-optimized (default: 1 MB)
```

Options

-i, --input <INPUT>

Input ZIP filename. Required.

-o, --output <OUTPUT>

Output ZIP filename. Required. Must have a `.zip` extension

--overwrite

Whether overwriting existing output is allowed.

--enable-sozip `auto|yes|no`

In `auto` mode, a file is seek-optimized only if its size is above the value of *--sozip-chunk-size*. In `yes` mode, all input files will be seek-optimized. In `no` mode, no input files will be seek-optimized.

--sozip-chunk-size <value>

Chunk size for a seek-optimized file. Defaults to 32768 bytes. The value is specified in bytes, or K and M suffix can be respectively used to specify a value in kilo-bytes or mega-bytes.

--sozip-min-file-size <value>

Minimum file size to decide if a file should be seek-optimized, in --enable-sozip=auto mode. Defaults to 1 MB byte. The value is specified in bytes, or K, M or G suffix can be respectively used to specify a value in kilo-bytes, mega-bytes or giga-bytes.

-q, --quiet

Do not output any informative message (only errors).

Multithreading

The *GDAL_NUM_THREADS* configuration option can be set to ALL_CPUS or a integer value to specify the number of threads to use for SOZip-compressed files. Defaults to ALL_CPUS.

Examples

Example 3: Create a, potentially seek-optimized, ZIP file sozip_optimized.zip from an existing ZIP file in.zip.

```
gdal vsi sozip optimize in.zip sozip_optimized.zip
```

"gdal vsi sozip list"

Description

List the files contained in the zip file in an output similar to Info-ZIP **unzip** utility, but with the addition of a column indicating whether each file is seek-optimized.

Synopsis

```
Usage: gdal vsi sozip list [OPTIONS] <INPUT>

List content of a ZIP file, with SOZIP related information.

Positional arguments:
  -i, --input <INPUT>     Input ZIP filename [required]

Common Options:
  -h, --help              Display help message and exit
  --json-usage            Display usage as JSON document and exit
  --config <KEY>=<VALUE>  Configuration option [may be repeated]
```

Options

-i, --input <INPUT>

Input ZIP filename. Required.

Examples

Example 4: List contents of my.zip.

```
gdal vsi sozip list my.zip
```

"gdal vsi sozip validate"

Description

Validates a SOZip file. Baseline ZIP validation is done in a light way, limited to being able to browse through ZIP records with the InfoZIP-based ZIP reader used by GDAL. But validation of the SOZip-specific aspects is done more thoroughly.

Synopsis

```
Usage: gdal vsi sozip list [OPTIONS] <INPUT>

List content of a ZIP file, with SOZIP related information.

Positional arguments:
  -i, --input <INPUT>     Input ZIP filename [required]

Common Options:
  -h, --help              Display help message and exit
  --json-usage            Display usage as JSON document and exit
  --config <KEY>=<VALUE>  Configuration option [may be repeated]
```

Options

-i, --input <INPUT>

Input ZIP filename. Required.

-q, --quiet

Do not output any informative message (only errors).

-v, --verbose

Turn on verbose mode.

Return status code

The program returns status code 0 in case of success, and non-zero in case of error (non-blocking errors emitted as warnings are considered as a successful execution).

Examples

Example 5: Validate my.zip.

```
gdal vsi sozip validate my.zip
```

5.1.8 Driver specific commands

5.1.8.1 gdal driver cog validate

Added in version 3.13.

Synopsis

```
Usage: gdal driver cog validate [OPTIONS] <DATASET>

Validate if a TIFF file is a Cloud Optimized GeoTIFF

Positional arguments:
  --input, --dataset <DATASET>  COG dataset [required]

Common Options:
```

(continues on next page)

(continued from previous page)

```
  -h, --help                    Display help message and exit
  --json-usage                  Display usage as JSON document and exit
  --config <KEY>=<VALUE>        Configuration option [may be repeated]
  -q, --quiet                   Quiet mode (no progress bar or warning message) [not␣
↪available in pipelines]

Options:
  --full-check <FULL-CHECK>     Whether to perform full check. FULL-CHECK=auto|yes|no␣
↪(default: auto)
```

Description

Validate if a TIFF file is a *Cloud Optimized GeoTIFF* and emits a report.

> **Note**
>
> This program requires the GDAL Python bindings to be available.

Program-Specific Options

--full-check `auto|yes|no`

Whether extensive checks, verifying leading and trailer bytes of strips or tiles, must be performed. In `auto` mode (the default), they are performed for local file, but not for remote files

Standard Options

-q, --quiet

Suppress progress bar and some warning messages.

Return status code

The program returns status code 0 in case of success, and non-zero in case of error (non-blocking errors emitted as warnings are considered as a successful execution).

Examples

Example 1

Check if a remote file is a valid COG file.

```
gdal driver cog validate /vsicurl/https://example.com/some.tif
```

5.1.8.2 gdal driver gpkg repack

Added in version 3.11.

Synopsis

```
Usage: gdal driver gpkg repack [OPTIONS] <DATASET>

Repack/vacuum in-place a GeoPackage dataset

Positional arguments:
  --dataset <DATASET>     GeoPackage dataset [required]

Common Options:
  -h, --help              Display help message and exit
  --json-usage            Display usage as JSON document and exit
  --config <KEY>=<VALUE>  Configuration option [may be repeated]
```

Description

Runs the `VACUUM` SQLite3 operation on a GeoPackage dataset to recover lost space due to updates or deletions.

Return status code

The program returns status code 0 in case of success, and non-zero in case of error (non-blocking errors emitted as warnings are considered as a successful execution).

Examples

Example 1

```
gdal driver gpkg repack my.gpkg
```

5.1.8.3 gdal driver gpkg validate

Added in version 3.13.

Synopsis

```
Usage: gdal driver gpkg validate [OPTIONS] <DATASET>

Validate conformance of a GeoPackage dataset against the GeoPackage specification

Positional arguments:
  --dataset <DATASET>     GeoPackage dataset [required]

Common Options:
  -h, --help              Display help message and exit
  --json-usage            Display usage as JSON document and exit
  --config <KEY>=<VALUE>  Configuration option [may be repeated]
  -q, --quiet             Quiet mode (no progress bar or warning message) [not available␣
↪in pipelines]

Options:
  --full-check            Whether to perform full check
  -v, --verbose           Turn on verbose mode
```

Description

Validate if GeoPackage dataset conforms to the GeoPackage specification.

> **Note**
>
> This program requires the GDAL Python bindings to be available.

Program-Specific Options

--full-check

Enable extensive checks, that may go beyond what is mandated by the GeoPackage specification

Standard Options

-v, --verbose

Enable verbose mode.

-q, --quiet

Suppress progress bar and some warning messages.

Return status code

The program returns status code 0 in case of success, and non-zero in case of error (non-blocking errors emitted as warnings are considered as a successful execution).

Examples

Example 1

Check if a GeoPackage file is conformant

```
gdal driver gpkg validate my.gpkg
```

5.1.8.4 gdal driver gti create

Added in version 3.11.

Synopsis

```
Usage: gdal driver gti create [OPTIONS] <INPUT>... <OUTPUT>

Create an index of raster datasets compatible with the GDAL Tile Index (GTI) driver.

Positional arguments:
  -i, --input <INPUT>                                          Input raster datasets␣
↪[may be repeated] [required]
  -o, --output <OUTPUT>                                        Output vector dataset␣
↪[required]

Common Options:
  -h, --help                                                   Display help message␣
```

(continues on next page)

(continued from previous page)

```
↪and exit
  --json-usage                                                  Display usage as JSON␣
↪document and exit
  --config <KEY>=<VALUE>                                        Configuration option␣
↪[may be repeated]
  -q, --quiet                                                   Quiet mode (no␣
↪progress bar or warning message) [not available in pipelines]

Options:
  -f, --of, --format, --output-format <OUTPUT-FORMAT>           Output format
  --co, --creation-option <KEY>=<VALUE>                         Creation option [may␣
↪be repeated]
  --lco, --layer-creation-option <KEY>=<VALUE>                  Layer creation option␣
↪[may be repeated]
  --overwrite                                                   Whether overwriting␣
↪existing output dataset is allowed
                                                                Mutually exclusive␣
↪with --update
  --update                                                      Whether to open␣
↪existing dataset in update mode
                                                                Mutually exclusive␣
↪with --overwrite
  --overwrite-layer                                             Whether overwriting␣
↪existing output layer is allowed
  --append                                                      Whether appending to␣
↪existing layer is allowed
  --nln, --output-layer <OUTPUT-LAYER>                          Output layer name
  --recursive                                                   Whether input␣
↪directories should be explored recursively.
  --filename-filter <FILENAME-FILTER>                           Pattern that the␣
↪filenames in input directories should follow ('*' and '?' wildcard) [may be repeated]
  --min-pixel-size <MIN-PIXEL-SIZE>                             Minimum pixel size in␣
↪term of geospatial extent per pixel (resolution) that a raster should have to be␣
↪selected.
  --max-pixel-size <MAX-PIXEL-SIZE>                             Maximum pixel size in␣
↪term of geospatial extent per pixel (resolution) that a raster should have to be␣
↪selected.
  --location-name <LOCATION-NAME>                               Name of the field␣
↪with the raster path (default: location)
  --absolute-path                                               Whether the path to␣
↪the input datasets should be stored as an absolute path
  --output-crs <OUTPUT-CRS>                                     Output CRS
  --metadata <KEY>=<VALUE>                                      Add dataset metadata␣
↪item [may be repeated]
  --skip-errors                                                 Skip errors related␣
↪to input datasets
  --profile <PROFILE>                                           Profile of output␣
↪dataset. PROFILE=none|STAC-GeoParquet (default: none)
  --base-url <BASE-URL>                                         Base URL for STAC-
↪GeoParquet href
  --id-method <ID-METHOD>                                       How to derive STAC-
↪GeoParquet 'id'. ID-METHOD=filename|md5|metadata-item (default: filename)
```

(continues on next page)

(continued from previous page)

```
  --id-metadata-item <ID-METADATA-ITEM>                          Name of metadata item␣
↪used to set STAC-GeoParquet 'id' (default: id)
  --xml-filename <XML-FILENAME>                                  Filename of the XML␣
↪Virtual Tile Index file to generate, that can be used as an input for the GDAL GTI /␣
↪Virtual Raster Tile Index driver

↪the virtual mosaic
  --nodata <NODATA>                                              Nodata value(s) of␣
↪the bands of the virtual mosaic [may be repeated]
  --color-interpretation <COLOR-INTERPRETATION>                  Color␣
↪interpretation(s) of the bands of the virtual mosaic. COLOR-
↪INTERPRETATION=red|green|blue|alpha|gray|undefined [may be repeated]
  --mask                                                         Defines that the␣
↪virtual mosaic has a mask band
  --fetch-metadata <gdal-metadata-name>,<field-name>,<field-type>  Fetch a metadata item␣
↪from source rasters and write it as a field in the index. [may be repeated]
```

Description

gdal driver gti create creates a vector dataset with a record for each input raster file, an attribute containing the filename, and a polygon geometry outlining the raster, to be used as input for the *GTI* driver.

This is an extension of *gdal raster index*.

There are two possibilities:

- either use directly a vector tile index generated by **gdal driver gti create** as the input of the GTI driver
- or generate a small XML .gti wrapper file, for easier use with non-file-based formats such as databases, or for vector formats that do not support setting layer metadata items.

Formats that support layer metadata are for example GeoPackage (`--of GPKG`), FlatGeoBuf (`--of FlatGeoBuf`) or PostGIS (`--of PG`)

Setting *--resolution* and *--ot* is recommended to avoid the GTI driver to have to deduce them by opening the first tile in the index. If the tiles have nodata or mask band, *--nodata* and *--mask* should also be set.

In a GTI context, the extent of all tiles referenced in the tile index must be expressed in a single CRS. Consequently, if input tiles may have different CRS, *--output-crs* must be specified.

The following options are available:

Standard options

-f, --of, --format, --output-format <OUTPUT-FORMAT>

Which output vector format to use. Allowed values may be given by `gdal --formats | grep vector | grep rw | sort`

--co, --creation-option <NAME>=<VALUE>

Many formats have one or more optional creation options that can be used to control particulars about the file created. For instance, the GeoTIFF driver supports creation options to control compression, and whether the file should be tiled.

May be repeated.

The creation options available vary by format driver, and some simple formats have no creation options at all. A list of options supported for a format can be listed with the *--formats* command line option but the documentation for the format is the definitive source of information on driver creation options. See *Raster drivers* format specific documentation for legal creation options for each format.

-lco <NAME>=<VALUE>

Layer creation option (format specific)

--overwrite

Allow program to overwrite existing target file or dataset. Otherwise, by default, **gdal** errors out if the target file or dataset already exists.

--update

Whether the output dataset must be opened in update mode. Implies that it already exists.

--overwrite-layer

Whether overwriting the existing output vector layer is allowed.

--append

Whether appending features to the existing output vector layer is allowed

-l, --nln, --layer <LAYER>

Provides a name for the output vector layer.

--recursive

Whether input directories should be explored recursively.

--filename-filter <FILENAME-FILTER>

Pattern that the filenames contained in input directories should follow. '*' is a wildcard character that matches any number of any characters including none. '?' is a wildcard character that matches a single character. Comparisons are done in a case insensitive way. Several filters may be specified.

For example: `--filename-filter "*.tif,*.tiff"`

--min-pixel-size <val>

Minimum pixel size in term of geospatial extent per pixel (resolution) that a raster should have to be selected. The pixel size is evaluated after reprojection of its extent to the target CRS defined by `--output-crs`.

--max-pixel-size <val>

Maximum pixel size in term of geospatial extent per pixel (resolution) that a raster should have to be selected. The pixel size is evaluated after reprojection of its extent to the target CRS defined by `--output-crs`.

-location-name <LOCATION-NAME>

The output field name to hold the file path/location to the indexed rasters. The default field name is `location`.

--absolute-path

The absolute path to the raster files is stored in the index file. By default the raster filenames will be put in the file exactly as they are specified on the command line.

--output-crs <OUTPUT-CRS>

Geometries of input files will be transformed to the desired target coordinate reference system. Default creates simple rectangular polygons in the same coordinate reference system as the input rasters.

--metadata <KEY>=<VALUE>

Write an arbitrary layer metadata item, for formats that support layer metadata. This option may be repeated.

--xml-filename <name>

Filename of the XML Virtual Tile Index file to generate, that can be used as an input for the GDAL GTI / Virtual Raster Tile Index driver. This can be useful when writing the tile index in a vector format that does not support writing layer metadata items.

--resolution <xres,<yres>

Target resolution in CRS unit per pixel.

Written in the XML Virtual Tile Index if *--xml-filename* is specified, or as RESX and RESY layer metadata items for formats that support layer metadata.

--bbox <xmin>,<ymin>,<xmax>,<ymax>

Target extent in CRS unit.

'x' is longitude values for geographic CRS and easting for projected CRS. 'y' is latitude values for geographic CRS and northing for projected CRS.

Written in the XML Virtual Tile Index if *--xml-filename* is specified, or as MINX, MINY, MAXX and MAXY layer metadata items for formats that support layer metadata.

--ot, --datatype, --output-data-type <datatype>

Data type of the tiles of the tile index: Byte, Int8, UInt16, Int16, UInt32, Int32, UInt64, Int64, Float32, Float64, CInt16, CInt32, CFloat32 or CFloat64

Written in the XML Virtual Tile Index if *--xml-filename* is specified, or as DATA_TYPE layer metadata item for formats that support layer metadata.

--band-count <val>

Number of bands of the tiles of the tile index.

Written in the XML Virtual Tile Index if *--xml-filename* is specified, or as BAND_COUNT layer metadata item for formats that support layer metadata.

A mix of tiles with N and N+1 bands is allowed, provided that the color interpretation of the (N+1)th band is alpha. The N+1 value must be written as the band count in that situation.

If *--nodata* or *--color-interpretation* are specified and have multiple values, the band count is also inferred from that number.

--nodata <val>[,<val>...]

Nodata value of the tiles of the tile index.

Written in the XML Virtual Tile Index if *--xml-filename* is specified, or as NODATA layer metadata item for formats that support layer metadata.

--color-interpretation <val>[,<val>...]

Color interpretation of of the tiles of the tile index: red, green, blue, alpha, gray, undefined.

Written in the XML Virtual Tile Index if *--xml-filename* is specified, or as COLOR_INTERPRETATION layer metadata item for formats that support layer metadata.

--mask

Whether tiles in the tile index have a mask band.

Written in the XML Virtual Tile Index if *--xml-filename* is specified, or as MASK_BAND layer metadata item for formats that support layer metadata.

--fetched-metadata <gdal_md_name>,<fld_name>,<fld_type>

Fetch a metadata item from the raster tile and write it as a field in the tile index.

<gdal_md_name> should be the name of the raster metadata item. {PIXEL_SIZE} may be used as a special name to indicate the pixel size.

<fld_name> should be the name of the field to create in the tile index.

<fld_type> should be the name of the type to create. One of String, Integer, Integer64, Real, Date, DateTime

This option may be repeated.

For example: --fetched-metadata TIFFTAG_DATETIME,creation_date,DateTime

Return status code

The program returns status code 0 in case of success, and non-zero in case of error (non-blocking errors emitted as warnings are considered as a successful execution).

Examples

Example 1

Make a tile index from GeoTIFF files, with metadata suitable for use by the GDAL GTI / Virtual Raster Tile Index driver.

```
gdal driver gti create --ot Byte --resolution=60,60 --band-count=3 --color-
↪interpretation=Red,Green,Blue *.tif tile_index.gti.gpkg
```

5.1.8.5 gdal driver openfilegdb repack

Added in version 3.11.

Synopsis

```
Usage: gdal driver openfilegdb repack [OPTIONS] <DATASET>

Repack a FileGeoDatabase dataset

Positional arguments:
  --dataset <DATASET>     FileGeoDatabase dataset [required]

Common Options:
  -h, --help              Display help message and exit
  --json-usage            Display usage as JSON document and exit
  --config <KEY>=<VALUE>  Configuration option [may be repeated]
  -q, --quiet             Quiet mode (no progress bar or warning message) [not available␣
↪in pipelines]
```

Description

Runs the a repack operation on a FileGeodatabase dataset to recover lost space due to updates or deletions.

Return status code

The program returns status code 0 in case of success, and non-zero in case of error (non-blocking errors emitted as warnings are considered as a successful execution).

Examples

Example 1

```
gdal driver openfilegdb repack my.gdb
```

5.1.8.6 gdal driver parquet create-metadata-file

Added in version 3.13.

Synopsis

```
Usage: gdal driver parquet create-metadata-file [OPTIONS] <INPUT>... <OUTPUT>

Create the _metadata file for a partitioned dataset

Positional arguments:
  --input <INPUT>         Input Parquet datasets (created by algorithm) [1.. values]␣
↪[required]
  --output <OUTPUT>       Output Parquet dataset [required]

Common Options:
  -h, --help              Display help message and exit
  --json-usage            Display usage as JSON document and exit
  --config <KEY>=<VALUE>  Configuration option [may be repeated]

Options:
  --overwrite             Whether overwriting existing output is allowed
```

Description

Creates a `_metadata` Parquet metadata-only file that contains the schema of the partitioned Parquet files and the path to them.

This program is automatically called by *gdal vector partition* for a Parquet output.

Return status code

The program returns status code 0 in case of success, and non-zero in case of error (non-blocking errors emitted as warnings are considered as a successful execution).

Examples

Example 1

```
gdal driver parquet create-metadata-file --input partitioned/0.parquet \
            --input partitioned/1.parquet --output partitioned/_metadata
```

5.1.8.7 gdal driver pdf list-layer

Added in version 3.11.

Synopsis

```
Usage: gdal driver pdf list-layers [OPTIONS] <INPUT>

List layers of a PDF dataset

Positional arguments:
  -i, --input <INPUT>                                    Input raster or vector dataset␣
↪[required]

Common Options:
  -h, --help                                             Display help message and exit
  --json-usage                                           Display usage as JSON document␣
↪and exit
  --config <KEY>=<VALUE>                                 Configuration option [may be␣
↪repeated]

Options:
  -f, --of, --format, --output-format <OUTPUT-FORMAT>  Output format. OUTPUT-
↪FORMAT=json|text (default: json)
```

Description

Return the list of layers of a PDF file, as a JSON array or a text list.

Return status code

The program returns status code 0 in case of success, and non-zero in case of error (non-blocking errors emitted as warnings are considered as a successful execution).

Examples

Example 1: Return the list of layers of a PDF file as a JSON array

```
gdal driver pdf list-layers autotest/gdrivers/data/pdf/adobe_style_geospatial.pdf
```

returns:

```
[
  "New_Data_Frame",
  "New_Data_Frame.Graticule",
  "Layers",
  "Layers.Measured_Grid",
  "Layers.Graticule"
]
```

Example 2: Return the list of layers of a PDF file as as a text list

```
gdal driver pdf list-layers --of=text autotest/gdrivers/data/pdf/adobe_style_geospatial.
↪pdf
```

returns:

```
New_Data_Frame
New_Data_Frame.Graticule
Layers
Layers.Measured_Grid
Layers.Graticule
```

5.1.8.8 gdal driver zarr add-georeferencing-convention

Added in version 3.14.

Synopsis

```
Usage: gdal driver zarr add-georeferencing-convention [OPTIONS] <INPUT> <CONVENTION>

Add a georeferencing convention to an existing ZARR dataset

Positional arguments:
  -i, --input <INPUT>        Input multidimensional raster dataset [required]
  --convention <CONVENTION>  Georeferencing convention. CONVENTION=GDAL|spatial_proj␣
↪[required]

Common Options:
  -h, --help                 Display help message and exit
  --json-usage               Display usage as JSON document and exit
  --config <KEY>=<VALUE>     Configuration option [may be repeated]
```

Description

Add (but not replace) a georeferencing convention to an existing ZARR dataset.

This has only effect on arrays for which georeferencing is recognized.

This can been used for example to add the Zarr spatial and geo-proj conventions by specifying `--convention` to `spatial_proj`.

Program-Specific Options

--convention `GDAL|spatial_proj`

Name of the georeferencing convention to add.

`GDAL` uses a `_CRS` attribute (cf *GDAL convention*).

`spatial_proj` uses the Zarr spatial and geo-proj conventions.

Return status code

The program returns status code 0 in case of success, and non-zero in case of error (non-blocking errors emitted as warnings are considered as a successful execution).

Examples

Example 1

title
Add the `spatial_proj` convention.

```
gdal driver zarr add-georeferencing-conventions my.zarr spatial_proj
```

5.2 "Traditional" applications

5.2.1 General

5.2.1.1 Syntax of arguments of command-line utilities

The following table describes the notation used to document the syntax of arguments of command-line utilities.

Notation	Description
Text without brackets or braces	Text that must be typed as shown
`<value>`	Placeholder for which a value must be substituted.
[Text inside square brackets]	Optional item.
{ Text inside braces }	Set of required items, separated by a vertical bar.
Vertical bar (`|`)	Separator between mutually exclusive items. At least one must be specified.
Ellipsis (`...`)	Placed after an item that can be repeated.

Example

Given the following synopsis:

```
my_utility [-wkt_format {WKT1|WKT2}] [-oo <NAME>=<VALUE>]...
           <datasetname>
```

The following command lines are valid:

```
my_utility foo.tif
```

```
my_utility -wkt_format WKT1 foo.tif
```

```
my_utility -oo FOO=BAR -oo BAR=BAZ foo.tif
```

5.2.2 Raster programs

5.2.2.1 Common options for raster programs

All GDAL command line programs support the following common options.

--version

Report the version of GDAL and exit.

--build

Report detailed information about GDAL in use.

--formats

List all raster formats supported by this GDAL build (read-only and read-write) and exit.

The format support is indicated as follows:

- `ro` is read-only driver
- `rw` is read or write (i.e. supports *GDALDriver::CreateCopy()*)
- `rw+` is read, write and update (i.e. supports *GDALDriver::Create()*)
- A `v` is appended for formats supporting virtual IO (/vsimem, /vsigzip, /vsizip, etc).
- A `s` is appended for formats supporting subdatasets.

The order in which drivers are listed is the one in which they are registered, which determines the order in which they are successively probed when opening a dataset. Most of the time, this order does not matter, but in some situations, several drivers may recognize the same file. The `-if` option of some utilities can be specified to restrict opening the dataset with a subset of drivers (generally one). Note that it does not force those drivers to open the dataset. In particular, some drivers have requirements on file extensions. Alternatively, the *GDAL_SKIP* configuration option can also be used to exclude one or several drivers.

--format `<format>`

List detailed information about a single format driver. The format should be the short name reported in the --formats list, such as GTiff.

--formats

List all drivers. Can be combined with `-json` switch of **gdalinfo** of since GDAL 3.10

--optfile `<filename>`

Read the named file and substitute the contents into the command line options list. Lines beginning with # will be ignored. Multi-word arguments may be kept together with double quotes. Multiple --optfiles may be used: --optfile file1 --optfile file2...

--config `<key> <value>`

Sets the named configuration keyword to the given value, as opposed to setting them as environment variables. Some common configuration keywords are *GDAL_CACHEMAX* (memory used internally for caching in megabytes) and *GDAL_DATA* (path of the GDAL "data" directory). Individual drivers may be influenced by other *configuration options*.

--debug `<value>`

Control what debugging messages are emitted. A value of ON will enable all debug messages. A value of OFF will disable all debug messages. Another value will select only debug messages containing that string in the debug prefix code.

--help-general

Gives a brief usage message for the generic GDAL command line options and exit.

Creating new files

Access an existing file to read it is generally quite simple. Just indicate the name of the file or dataset on the command line. However, creating a file is more complicated. It may be necessary to indicate the format to create, various creation options affecting how it will be created and perhaps a coordinate system to be assigned. Many of these options are handled similarly by different GDAL utilities, and are introduced here.

-of <format>

Select the format to create the new file as. The formats are assigned short names such as GTiff (for GeoTIFF) or HFA (for Erdas Imagine). The list of all format codes can be listed with the *--formats* switch. Only formats list as (rw) (read-write) can be written.

If not specified, the format is guessed from the extension.

-co <NAME>=<VALUE>

Many formats have one or more optional creation options that can be used to control particulars about the file created. For instance, the GeoTIFF driver supports creation options to control compression, and whether the file should be tiled.

The creation options available vary by format driver, and some simple formats have no creation options at all. A list of options supported for a format can be listed with the *--format* command line option but the documentation for the format is the definitive source of information on driver creation options. See *Raster drivers* format specific documentation for legal creation options for each format.

-a_srs <srs>

-s_srs <srs>

-t_srs <srs>

Several utilities (e.g. **gdal_translate** and **gdalwarp**) include the ability to specify coordinate systems with command line options like *-a_srs* (assign SRS to output), *-s_srs* (source SRS) and *-t_srs* (target SRS). These utilities allow the coordinate system (SRS = spatial reference system) to be assigned in a variety of formats.

- NAD27|NAD83|WGS84|WGS72

  These common geographic (lat/long) coordinate systems can be used directly by these names.

- EPSG:n

  Coordinate systems (projected or geographic) can be selected based on their EPSG codes. For instance, EPSG:27700 is the British National Grid. A list of EPSG coordinate systems can be found in the GDAL data files gcs.csv and pcs.csv.

- PROJ.4 definition

  A PROJ.4 definition string can be used as a coordinate system. Take care to keep the proj.4 string together as a single argument to the command (usually by double quoting).

  For instance +proj=utm +zone=11 +datum=WGS84.

- OpenGIS Well Known Text

  The Open GIS Consortium has defined a textual format for describing coordinate systems as part of the Simple Features specifications. This format is the internal working format for coordinate systems used in GDAL. The name of a file containing a WKT coordinate system definition may be used a coordinate system argument, or the entire coordinate system itself may be used as a command line option (though escaping all the quotes in WKT is quite challenging).

- ESRI Well Known Text

  ESRI uses a slight variation on OGC WKT format in their ArcGIS product (ArcGIS .prj files), and these may be used in a similar manner o WKT files, but the filename should be prefixed with ESRI::.

  For example, *"ESRI::NAD 1927 StatePlane Wyoming West FIPS 4904.prj"*.

- Spatial References from URLs

  For example http://spatialreference.org/ref/user/north-pacific-albers-conic-equal-area/.

- `filename`

  File containing WKT, PROJ.4 strings, or XML/GML coordinate system definitions can be provided.

5.2.2.2 gdal-config (Unix)

Determines various information about a GDAL installation.

Synopsis

```
gdal-config [OPTIONS]
Options:
        [--prefix[=DIR]]
        [--libs]
        [--cflags]
        [--version]
        [--ogr-enabled]
        [--formats]
```

Description

This utility script (available on Unix systems) can be used to determine various information about a GDAL installation. It is normally just used by configure scripts for applications using GDAL but can be queried by an end user.

--prefix

the top level directory for the GDAL installation.

--libs

The libraries and link directives required to use GDAL.

--cflags

The include and macro definition required to compiled modules using GDAL.

--version

Reports the GDAL version.

--ogr-enabled

Reports "yes" or "no" to standard output depending on whether OGR is built into GDAL.

--formats

Reports which formats are configured into GDAL to stdout.

5.2.2.3 gdal2tiles

Synopsis

```
gdal2tiles [--help] [--help-general]
              [--legacy]
              [-p <profile>] [-r resampling] [-s <srs>] [-z <zoom>]
              [-e] [-a nodata] [-v] [-q] [-h] [-k] [-n] [-u <url>]
              [-w <webviewer>] [-t <title>] [-c <copyright>]
              [--processes=<NB_PROCESSES>] [--mpi] [--xyz]
              [--tilesize=<PIXELS>] --tiledriver=<DRIVER> [--tmscompatible]
              [--excluded-values=<EXCLUDED_VALUES>]
```

(continues on next page)

(continued from previous page)

```
                [--excluded-values-pct-threshold=<EXCLUDED_VALUES_PCT_THRESHOLD>]
                [--nodata-values-pct-threshold=<NODATA_VALUES_PCT_THRESHOLD>]
                [-g <googlekey] [-b <bingkey>] <input_file> [<output_dir>] [<COMMON_
↪OPTIONS>]
```

Description

Warning

Starting with GDAL 3.13, **gdal2tiles** is deprecated, and by default is remapped to *gdal raster tile*. For now, you may force the use of the legacy code by specifying *--legacy*, but legacy mode will be removed in GDAL 3.15. If you find yourself to need legacy mode and cannot find workarounds using gdal raster tile, please file a ticket at https://github.com/OSGeo/GDAL

This utility generates a directory with small tiles and metadata, following the OSGeo Tile Map Service Specification. Simple web pages with viewers based on Google Maps, OpenLayers and Leaflet are generated as well - so anybody can comfortably explore your maps on-line and you do not need to install or configure any special software (like MapServer) and the map displays very fast in the web browser. You only need to upload the generated directory onto a web server.

GDAL2Tiles also creates the necessary metadata for Google Earth (KML SuperOverlay), in case the supplied map uses EPSG:4326 projection.

World files and embedded georeferencing is used during tile generation, but you can publish a picture without proper georeferencing too.

Note

Inputs with non-Byte data type (i.e. `Int16`, `UInt16`,...) will be clamped to the `Byte` data type, causing wrong results. To avoid this it is necessary to rescale input to the `Byte` data type using *gdal_translate* utility.

Note

Config options of the input drivers may have an effect on the output of gdal2tiles. An example driver config option is GDAL_PDF_DPI, which can be found at *Configuration options*

Note

gdal2tiles is a Python utility, and is only available if GDAL Python bindings are available.

Tip

Equivalent in new "gdal" command line interface:

See *gdal raster tile*

--help

Show this help message and exit

--help-general

Gives a brief usage message for the generic GDAL commandline options and exit.

--legacy

Added in version 3.13.

Force the use of the legacy code base. Since GDAL 3.13, by default, gdal2tiles is implemented using *gdal raster tile*.

-p <PROFILE>, **--profile**=<PROFILE>

Tile cutting profile (mercator, geodetic, raster) - default 'mercator' (Google Maps compatible).

Starting with GDAL 3.2, additional profiles are available from tms_XXXX.json files placed in GDAL data directory (provided all zoom levels use same origin, tile dimensions, and resolution between consecutive zoom levels vary by a factor of two).

-r <RESAMPLING>, **--resampling**=<RESAMPLING>

Resampling method (average, near, bilinear, cubic, cubicspline, lanczos, mode, max, min, med, q1, q3) - default 'average'.

-s <SRS>, **--s_srs**=<SRS>

The spatial reference system used for the source input data.

--xyz

Generate XYZ tiles (OSM Slippy Map standard) instead of TMS. In the default mode (TMS), tiles at y=0 are the southern-most tiles, whereas in XYZ mode (used by OGC WMTS too), tiles at y=0 are the northern-most tiles.

Added in version 3.1.

-d, --tmscompatible

When using the geodetic profile, specifies the base resolution as 0.703125 or 2 tiles at zoom level 0.

-z <ZOOM>, **--zoom**=<ZOOM>

Zoom levels to render (format:'2-5', '10-' or '10').

-e, --resume

Resume mode. Generate only missing files.

-a <NODATA>, **--srcnodata**=<NODATA>

Value in the input dataset considered as transparent. If the input dataset had already an associate nodata value, it is overridden by the specified value.

-v, --verbose

Generate verbose output of tile generation.

Starting with GDAL 3.7, that verbose output is emitted through the `logging.getLogger("gdal2tiles")` object.

-x, --exclude

Exclude transparent tiles from result tileset.

-q, --quiet

Disable messages and status to stdout

--processes=<NB_PROCESSES>

Number of parallel processes to use for tiling, to speed-up the computation.

--mpi

Added in version 3.5.

Assume launched by mpiexec, enable MPI parallelism and ignore --processes. Requires working MPI environment and the MPI for Python (mpi4py) package. User should set GDAL_CACHEMAX to an appropriate cache size per process based on memory per node and the number of processes launched per node.

> **Warning**
>
> --mpi mode is not supported in *gdal raster tile* non-legacy mode. You may specify `--legacy` to go on, but this legacy mode is going to be removed in GDAL 3.15.

--tilesize=<PIXELS>

Added in version 3.1.

Width and height in pixel of a tile. Default is 256.

--tiledriver=<DRIVER>

Which output driver to use for the tiles, determines the file format of the tiles. Currently PNG, WEBP and JPEG (JPEG added in GDAL 3.9) are supported. Default is PNG. Additional configuration for the WEBP and JPEG drivers are documented below.

Added in version 3.6.

--excluded-values=<EXCLUDED_VALUES>

Comma-separated tuple of values (thus typically "R,G,B"), that are ignored as contributing source pixels during resampling. The number of values in the tuple must be the same as the number of bands, excluding the alpha band. Several tuples of excluded values may be specified using the "(R1,G1,B2),(R2,G2,B2)" syntax. Only taken into account by Average currently. This concept is a bit similar to nodata/alpha, but the main difference is that pixels matching one of the excluded value tuples are still considered as valid, when determining the target pixel validity/density.

Added in version 3.9.

--excluded-values-pct-threshold=EXCLUDED_VALUES_PCT_THRESHOLD

Minimum percentage of source pixels that must be set at one of the --excluded-values to cause the excluded value, that is in majority among source pixels, to be used as the target pixel value. Default value is 50(%)

Added in version 3.9.

--nodata-values-pct-threshold=<NODATA_VALUES_PCT_THRESHOLD>

Minimum percentage of source pixels that must be at nodata (or alpha=0 or any other way to express transparent pixel) to cause the target pixel value to be transparent. Default value is 100 (%), which means that a target pixel is transparent only if all contributing source pixels are transparent. Only taken into account for average resampling.

Added in version 3.9.

-h, --help

Show help message and exit.

--version

Show program's version number and exit.

KML (Google Earth) options

Options for generated Google Earth SuperOverlay metadata

-k, --force-kml

Generate KML for Google Earth - default for 'geodetic' profile and 'raster' in EPSG:4326. For a dataset with different projection use with caution!

-n, --no-kml

Avoid automatic generation of KML files for EPSG:4326.

-u <URL>, **--url**=<URL>

URL address where the generated tiles are going to be published.

Web viewer options

Options for generated HTML viewers a la Google Maps

-w <WEBVIEWER>, **--webviewer**=<WEBVIEWER>

Web viewer to generate (all, google, openlayers, leaflet, mapml, none) - default 'all'.

-t <TITLE>, **--title**=<TITLE>

Title of the map.

-c <COPYRIGHT>, **--copyright**=<COPYRIGHT>

Copyright for the map.

-g <GOOGLEKEY>, **--googlekey**=<GOOGLEKEY>

Google Maps API key from https://developers.google.com/maps/get-started.

-b <BINGKEY>, **--bingkey**=<BINGKEY>

Bing Maps API key from https://www.bingmapsportal.com/

MapML options

MapML support is new to GDAL 3.2. When --webviewer=mapml is specified, --xyz is implied, as well as --tmscompatible if --profile=geodetic.

The following profiles are supported:

- mercator: mapped to OSMTILE MapML tiling scheme
- geodetic: mapped to WGS84 MapML tiling scheme
- APSTILE: from the tms_MapML_APSTILE.json data file

The generated MapML file in the output directory is `mapml.mapml`

Available options are:

--mapml-template=<filename>

Filename of a template mapml file where variables will be substituted. If not specified, the generic template_tiles.mapml file from GDAL data resources will be used

The --url option is also used to substitute `${URL}` in the template MapML file.

WEBP options

WEBP tiledriver support is new to GDAL 3.6. It is enabled by using --tiledriver=WEBP.

The following configuration options are available to further customize the WebP output:

--webp-quality=<QUALITY>
: QUALITY is a integer between 1-100. Default is 75.

--webp-lossless
: Use WEBP lossless compression, default is lossy

> **Note**
>
> GDAL *WEBP driver* documentation can be consulted

JPEG options

JPEG tiledriver support is new to GDAL 3.9. It is enabled by using --tiledriver=JPEG.

Note that JPEG does not support transparency, hence edge tiles will display black pixels in areas not covered by the source raster.

The following configuration options are available to further customize the JPEG output:

---jpeg-quality=JPEG_QUALITY
: QUALITY is a integer between 1-100. Default is 75.

Return status code

The program returns status code 0 in case of success, and non-zero in case of error (non-blocking errors emitted as warnings are considered as a successful execution).

Examples

Example 1: Basic example

```
gdal2tiles --zoom=2-5 input.tif output_folder
```

Example 2: MapML generation

```
gdal2tiles --zoom=16-18 -w mapml -p APSTILE --url "https://example.com" input.tif output_
↪folder
```

Example 3: MPI example

```
mpiexec -n $NB_PROCESSES gdal2tiles --mpi --config GDAL_CACHEMAX 500 --zoom=2-
↪5 input.tif output_folder
```

5.2.2.4 gdal2xyz

Synopsis

```
gdal2xyz [--help] [--help-general]
    [-skip <factor>]
    [-srcwin <xoff> <yoff> <xsize> <ysize>]
    [-b <band>]... [-allbands]
    [-skipnodata]
    [-csv]
    [-srcnodata <value>] [-dstnodata <value>]
    <src_dataset> <dst_dataset>
```

Description

The **gdal2xyz** utility can be used to translate a raster file into xyz format. *gdal2xyz* can be used as an alternative to *gdal_translate of=xyz*. Features include:

- Select more then one band
- Skip or replace nodata value
- Return the output as numpy arrays.

Note

gdal2xyz is a Python utility, and is only available if GDAL Python bindings are available.

Tip

Equivalent in new "gdal" command line interface:

See *gdal raster convert* with `--of XYZ`.

--help

Show this help message and exit

--help-general

Gives a brief usage message for the generic GDAL commandline options and exit.

-skip

How many rows/cols to skip in each iteration.

-srcwin <xoff> <yoff> <xsize> <ysize>

Selects a subwindow from the source image for copying based on pixel/line location.

-b, -band <band>

Select band *band* from the input spectral bands for output. Bands are numbered from 1 in the order spectral bands are specified. Multiple **-b** switches may be used. When no -b switch is used, the first band will be used. In order to use all input bands set *-allbands* or *-b 0*.

-allbands

Select all input bands.

-csv

Use comma instead of space as a delimiter.

-skipnodata

Exclude the output lines with nodata value (as determined by srcnodata)

-srcnodata

The nodata value of the dataset (for skipping or replacing) Default (*None*) - Use the dataset nodata value; *Sequence/Number* - Use the given nodata value (per band or per dataset).

-dstnodata

Replace source nodata with a given nodata. Has an effect only if not setting *-skipnodata*. Default(*None*) - Use *srcnodata*, no replacement; *Sequence/Number* - Replace the *srcnodata* with the given nodata value (per band or per dataset).

-h, --help

Show help message and exit.

<src_dataset>

The source dataset name. It can be either file name, URL of data source or subdataset name for multi-dataset files.

<dst_dataset>

The destination file name.

Examples

Example 1

```
gdal2xyz -b 1 -b 2 -dstnodata 0 input.tif output.txt
```

To create a text file in *xyz* format from the input file *input.tif*. The first columns, x and y, are the coordinates of the centers of each cell. The remaining columns represent the first and second bands. We also replace the dataset nodata values with zeros.

Return status code

The program returns status code 0 in case of success, and non-zero in case of error (non-blocking errors emitted as warnings are considered as a successful execution).

Caveats

gdal2xyz output values with a limited precision. Use `gdal_translate -of XYZ` if more precision is desired.

5.2.2.5 gdal_calc

Synopsis

```
gdal_calc [--help] [--help-general]
             --calc=expression --outfile=<out_filename> [-A <filename>]
             [--A_band=<n>] [-B...-Z <filename>] [<other_options>]
```

DESCRIPTION

Command line raster calculator with numpy syntax. Use any basic arithmetic supported by numpy arrays such as +, -, *, and / along with logical operators such as >. Note that all files must have the same dimensions (unless the `--extent` option is used), but no projection checking is performed (unless the `--projectionCheck` option is used).

> **Note**
>
> gdal_calc is a Python utility, and is only available if GDAL Python bindings are available.

> **Tip**
>
> Equivalent in new "gdal" command line interface:
>
> See *gdal raster calc*.

--help

Show this help message and exit

--help-general

Gives a brief usage message for the generic GDAL commandline options and exit.

--calc=<expression>

Calculation in numpy syntax using +, -, /, *, or any numpy array functions (i.e. `log10()`). Multiple `--calc` options can be listed to produce a multiband file (GDAL >= 3.2). See *Example 10*.

-A <filename>

Input GDAL raster file, you can use any letter (a-z, A-Z). (lower case supported since GDAL 3.3)

A letter may be repeated, or several values (separated by space) can be provided (GDAL >= 3.3). The effect will be to create a 3D numpy array. Since GDAL 3.5, wildcard exceptions (using ?, *) are supported for all shells/platforms. In such a case, the calculation formula must use this input as a 3D array and must return a 2D array (see *Example 3*). If the calculation does not return a 2D array an error will be generated.

--A_band=<n>

Number of raster band for file A (default 1).

--outfile=<filename>

Output file to generate or fill.

--NoDataValue=<value>

Output NoDataValue (default datatype specific value). To indicate not setting a NoDataValue use --NoDataValue=none (GDAL >= 3.3)

> **Note**
>
> Using the Python API: `None` value will indicate default datatype specific value. `'none'` value will indicate not setting a NoDataValue.

--hideNoData

Added in version 3.3.

Ignores the input bands NoDataValue. By default, the input bands NoDataValue are not participating in the calculation. By setting this setting - no special treatment will be performed on the input NoDataValue. and they

will be participating in the calculation as any other value. The output will not have a set NoDataValue, unless you explicitly specified a specific value by setting --NoDataValue=<value>.

--type=<datatype>

Output datatype, must be one of [`Byte`, `Int8`, `UInt16`, `Int16`, `UInt32`, `Int32`, `UInt64`, `Int64`, `Float64`, `Float32`, `CInt16`, `CInt32`, `CFloat64`, `CFloat32`].

> **Note**
>
> Despite the datatype set using `--type`, when doing intermediate arithmetic operations using operands of the same type, the operation result will honor the original datatype. This may lead into unexpected results in the final result.

> **Note**
>
> UInt64, Int64, CInt16, CInt32, CFloat32, CFloat64 have been added in GDAL 3.5.3 Int8 has been added in GDAL 3.7

--format=<gdal_format>

GDAL format for output file.

--color-table=<filename>

Allows specifying a filename of a color table (or a ColorTable object) (with Palette Index interpretation) to be used for the output raster. Supported formats: txt (i.e. like gdaldem, but color names are not supported), qlr, qml (i.e. exported from QGIS)

--extent=<option>

Added in version 3.3.

This option determines how to handle rasters with different extents. This option is mutually exclusive with the *projwin* option, which is used for providing a custom extent.

For all the options below the pixel size (resolution) and SRS (Spatial Reference System) of all the input rasters must be the same.

`ignore` (default) - only the dimensions of the rasters are compared. if the dimensions do not agree the operation will fail.

`fail` - the dimensions and the extent (bounds) of the rasters must agree, otherwise the operation will fail.

`union` - the extent (bounds) of the output will be the minimal rectangle that contains all the input extents.

`intersect` - the extent (bounds) of the output will be the maximal rectangle that is contained in all the input extents.

--projwin <ulx> <uly> <lrx> <lry>

Added in version 3.3.

This option provides a custom extent for the output, it is mutually exclusive with the *extent* option.

--projectionCheck

Added in version 3.3.

By default, no projection checking will be performed. By setting this option, if the projection is not the same for all bands then the operation will fail.

--creation-option=<option>

Passes a creation option to the output format driver. Multiple options may be listed. See format specific documentation for legal creation options for each format.

--co=<option>

The same as *creation-option*.

--allBands=[a-z, **A-Z**]

Apply the expression to all bands of a given raster. When `--allBands` is used, `--calc` may be specified only once. See *Example 11* and *Example 12*.

--overwrite

Overwrite output file if it already exists. Overwriting must be understood here as deleting and recreating the file from scratch. Note that if this option is *not* specified and the output file already exists, it will be updated in place.

--debug

Print debugging information.

--quiet

Suppress progress messages.

Return status code

The program returns status code 0 in case of success, and non-zero in case of error (non-blocking errors emitted as warnings are considered as a successful execution).

Python options

Added in version 3.3.

The following options are available by using the Python interface of **gdal_calc**. They are not available using the command prompt.

user_namespace

A dictionary of custom functions or other names to be available for use in the Calc expression.

return_ds

If enabled, the output dataset will be returned from the function and not closed.

color_table

Allows specifying a ColorTable object (with Palette Index interpretation) to be used for the output raster.

Examples

Example 1: Average of two files

```
gdal_calc -A input1.tif -B input2.tif --outfile=result.tif --calc="(A+B)/2"
```

Caution

If A and B inputs both have integer data types, integer division will be performed. To avoid this, you can convert one of the operands to a floating point type before the division operation.

```
gdal_calc -A input.tif -B input2.tif --outfile=result.tif --calc="(A.astype(numpy.
↪float64) + B) / 2"
```

Example 2: Summing three files

```
gdal_calc -A input1.tif -B input2.tif -C input3.tif --outfile=result.tif --calc="A+B+C"
```

Example 3: Combining three files into a 3D array and summing

```
gdal_calc -A input1.tif -A input2.tif -A input3.tif --outfile=result.tif --calc="numpy.
↪sum(A,axis=0)".
```

Example 4: Average of three files

```
gdal_calc -A input1.tif -B input2.tif -C input3.tif --outfile=result.tif --calc="(A+B+C)/
↪3"
```

Example 5: Average of three files, using 3D array

```
gdal_calc -A input1.tif input2.tif input3.tif --outfile=result.tif --calc="numpy.
↪average(a,axis=0)".
```

Example 6: Maximum of three files

```
gdal_calc -A input1.tif -B input2.tif -C input3.tif --outfile=result.tif --calc="numpy.
↪max((A,B,C),axis=0)"
```

Example 7: Maximum of three files, using a 3D array

```
gdal_calc -A input1.tif input2.tif input3.tif --outfile=result.tif --calc="numpy.max(A,
↪axis=0)"
```

Example 8: Setting values of zero and below to NODATA

```
gdal_calc -A input.tif --outfile=result.tif --calc="A*(A>0)" --NoDataValue=0
```

Example 9: Using logical operator to keep a range of values from input

```
gdal_calc -A input.tif --outfile=result.tif --calc="A*logical_and(A>100,A<150)"
```

Example 10: Performing two calculations and storing results in separate bands

```
gdal_calc -A input.tif --A_band=1 -B input.tif --B_band=2 \
  --outfile=result.tif --calc="(A+B)/2" --calc="B*logical_and(A>100,A<150)"
```

Example 11: Add a raster to each band in a 3-band raster

```
gdal_calc -A 3band.tif -B 1band.tif --outfile result.tif --calc "A+B" --allBands A
```

The result will have three bands, where each band contains the values of `1band.tif` added to the corresponding band in `3band.tif`.

Example 12: Add two three-band rasters

```
gdal_calc -A 3band_a.tif -B 3band_b.tif --outfile result.tif --calc "A+B" --allBands A --
↪allBands B
```

The result will have three bands, where each band contains the values of the corresponding band of `3band_a.tif` added to the corresponding band of `3band_b.tif`.

5.2.2.6 gdal_contour

Synopsis

```
gdal_contour [--help] [--help-general]
             [-b <band>] [-a <attribute_name>] [-amin <attribute_name>] [-amax
↪<attribute_name>]
             [-3d] [-inodata] [-snodata <n>] [-f <formatname>] [-i <interval>]
             [-dsco <NAME>=<VALUE>]... [-lco <NAME>=<VALUE>]...
             [-off <offset>] [-fl <level> <level>...] [-e <exp_base>]
             [-nln <outlayername>] [-q] [-p] [-gt <n>|unlimited]
             <src_filename> <dst_filename>
```

Description

The **gdal_contour** generates a vector contour file from the input raster elevation model (DEM).

The contour line-strings are oriented consistently and the high side will be on the right, i.e. a line string goes clockwise around a top.

> **Tip**
>
> Equivalent in new "gdal" command line interface:
>
> See *gdal raster contour*.

--help

Show this help message and exit

--help-general

Gives a brief usage message for the generic GDAL commandline options and exit.

-q, --quiet

Suppress progress messages and other non-error output.

-b <band>

Picks a particular band to get the DEM from. Defaults to band 1.

-a <name>

Provides a name for the attribute in which to put the elevation. If not provided no elevation attribute is attached. Ignored in polygonal contouring (*-p*) mode.

-amin <name>

Provides a name for the attribute in which to put the minimum elevation of contour polygon. If not provided no minimum elevation attribute is attached. Ignored in default line contouring mode.

-amax <name>

Provides a name for the attribute in which to put the maximum elevation of contour polygon. If not provided no maximum elevation attribute is attached. Ignored in default line contouring mode.

-3d

Force production of 3D vectors instead of 2D. Includes elevation at every vertex.

-inodata

Ignore any nodata value implied in the dataset - treat all values as valid. Cannot be used together with *-snodata*.

-snodata <value>

Input pixel value to treat as "nodata". Cannot be used together with *-inodata*.

-f <format>

Create output in a particular format.

If not specified, the format is guessed from the extension (previously was ESRI Shapefile).

-dsco <NAME>=<VALUE>

Dataset creation option (format specific)

-lco <NAME>=<VALUE>

Layer creation option (format specific)

-i <interval>

Elevation interval between contours. Must specify either *-i* or *-fl* or *-e*. The first contour will be generated at the first multiple of `interval` which is greater than the raster minimum value.

-off <offset>

Offset from zero relative to which to interpret intervals.

For example, *-i 100* requests contours at ...-100, 0, 100... Further adding *-off 25* makes that request instead ...-75, 25, 125...

-fl <level>

Name one or more "fixed levels" to extract, in ascending order separated by spaces.

-e <base>

Generate levels on an exponential scale: *base* ^ *k*, for *k* an integer. Must specify either -i or -fl or -e.

-nln <name>

Provide a name for the output vector layer. Defaults to "contour".

-p

Generate contour polygons rather than contour lines.

When this mode is selected the polygons are created for values between each level specified by *-i* or *-fl* or *-e*, in case *-fl* is used alone at least two fixed levels must be specified.

The minimum and maximum values from the raster are not automatically added to the fixed levels list but the special values `MIN` and `MAX` (case insensitive) can be used to include them.

-gt <n>

Group n features per transaction (default 100 000). Increase the value for better performance when writing into DBMS drivers that have transaction support. `n` can be set to unlimited to load the data into a single transaction. If set to 0, no explicit transaction is done.

Added in version 3.10.

Return status code

The program returns status code 0 in case of success, and non-zero in case of error (non-blocking errors emitted as warnings are considered as a successful execution).

C API

Functionality of this utility can be done from C with *GDALContourGenerate()*.

Examples

Example 1

title
Creating contours from a DEM

```
gdal_contour -a elev dem.tif contour.shp -i 10.0
```

This would create 10-meter contours from the DEM data in `dem.tif` and produce a shapefile in `contour.shp|shx|dbf` with the contour elevations in the `elev` attribute.

Example 2

title
Creating polygonal contours from a DEM

```
$ cat test.asc
ncols        2
nrows        2
xllcorner    0
yllcorner    0
cellsize     1
4 15
25 36

$ gdal_contour test.asc -f GeoJSON /vsistdout/ -i 10 -p -amin min -amax max
```

This would create 10-meter polygonal contours from the DEM data in `test.asc` and produce a GeoJSON output with the contour min and max elevations in the `min` and `max` attributes, including the minimum and maximum values from the raster.

```

    ]
}
```

Example 3

title
Creating contours from a DEM with fixed levels

```
$ cat test.asc
ncols        2
nrows        2
xllcorner    0
yllcorner    0
cellsize     1
4 15
25 36

$ gdal_contour test.asc -f GeoJSON /vsistdout/ -fl 10 20 -p -amin min -amax max
```

This would create a single polygonal contour between 10 and 20 meters from the DEM data in `test.asc` and produce a GeoJSON output with the contour min and max elevations in the `min` and `max` attributes.

If the minimum and maximum values from the raster are desired, the special values `MIN` and `MAX` (case insensitive) can be used:

```
$ cat test.asc
ncols        2
nrows        2
xllcorner    0
yllcorner    0
cellsize     1
4 15
25 36

$ gdal_contour test.asc -f GeoJSON /vsistdout/ -fl MIN 10 20 MAX -p -amin min -amax max
```

This would create three polygonal contours from the DEM data in `test.asc` and produce a GeoJSON output with the contour min and max elevations in the `min` and `max` attributes, the values of these fields will be: (4.0, 10.0), (10, 20.0) and (20.0, 36.0).

Example 4

title
Creating contours from a DEM specifying an interval and fixed levels at the same time

```
$ cat test.asc
ncols        2
nrows        2
xllcorner    0
yllcorner    0
cellsize     1
4 15
25 36

$ gdal_contour test.asc -f GeoJSON /vsistdout/ -i 10 -fl 15 -p -amin min -amax max
```

Creates contours at regular 10 meter intervals and adds extra contour for a fixed 15 m level. Finally turns areas between the contours into polygons with the contour min and max elevations in the `min` and `max` attributes, the values of these fields will be: (4.0, 10.0), (10, 15.0), (15, 20.0), (20.0, 30.0) and (30.0, 36.0).

5.2.2.7 gdal_create

Synopsis

```
Usage: gdal_create [--help] [--long-usage] [--help-general]
                   [-ot Byte|Int8|[U]Int{16|32|64}|CInt{16|32}|[C]Float{32|64}]
                   [-of <output_format>] [-outsize <xsize> <ysize>]
                   [-bands <count>] [-burn <value>]... [-a_srs <srs_def>]
                   [-a_ullr <ulx> <uly> <lrx> <lry>] [-a_nodata <value>]
                   [-mo <NAME>=<VALUE>]... [-co <NAME>=<VALUE>]... [--quiet]
                   [-if <input_dataset>]
                   <out_dataset>
```

Description

The **gdal_create** utility can be used to initialize a new raster file, from its dimensions, band count and set various parameters, such as CRS, geotransform, nodata value, metadata. It can be used also in special cases, like creating a PDF file from a XML composition file.

> **Tip**
>
> Equivalent in new "gdal" command line interface:
>
> See *gdal raster create*.

--help
Show this help message and exit

--help-general
Gives a brief usage message for the generic GDAL commandline options and exit.

-q, --quiet
Suppress progress messages and other non-error output.

-ot <type>

Force the output image bands to have a specific data type supported by the driver, which may be one of the following: `Byte`, `Int8`, `UInt16`, `Int16`, `UInt32`, `Int32`, `UInt64`, `Int64`, `Float32`, `Float64`, `CInt16`, `CInt32`, `CFloat32` or `CFloat64`.

-of <format>

Select the output format. If not specified, the format is guessed from the extension. Use the short format name.

-outsize <xsize> <ysize>

Set the size of the output file in pixels. First value is width. Second one is height.

-bands <count>

Number of bands. Defaults to 1 if -outsize is specified, or 0 otherwise.

-burn <value>

A fixed value to burn into a band. A list of *-burn* options can be supplied, one per band (the first value will apply to the first band, the second one to the second band, etc.). If a single value is specified, it will apply to all bands.

-a_srs <srs_def>

Override the projection for the output file. The<srs_def> may be any of the usual GDAL/OGR forms, complete WKT, PROJ.4, EPSG:n or a file containing the WKT. No reprojection is done.

-a_ullr <ulx> <uly> <lrx> <lry>

Assign the georeferenced bounds of the output file.

-a_nodata <value>

Assign a specified nodata value to output bands.

-mo <META-TAG>=<VALUE>

Passes a metadata key and value to set on the output dataset if possible.

-co <NAME>=<VALUE>

Many formats have one or more optional creation options that can be used to control particulars about the file created. For instance, the GeoTIFF driver supports creation options to control compression, and whether the file should be tiled.

The creation options available vary by format driver, and some simple formats have no creation options at all. A list of options supported for a format can be listed with the *--format* command line option but the documentation for the format is the definitive source of information on driver creation options. See *Raster drivers* format specific documentation for legal creation options for each format.

-if <input_dataset>

Added in version 3.3.

Name of GDAL input dataset that serves as a template for default values of options -outsize, -bands, -ot, -a_srs, -a_ullr and -a_nodata. Note that the pixel values will *not* be copied.

<out_dataset>

The destination file name.

Return status code

The program returns status code 0 in case of success, and non-zero in case of error (non-blocking errors emitted as warnings are considered as a successful execution).

Examples

Example 1: Initialize a new GeoTIFF file with a uniform value of 10

```
gdal_create -outsize 20 20 -a_srs EPSG:4326 -a_ullr 2 50 3 49 -burn 10 out.tif
```

Example 2: Create a PDF file from a XML composition file

```
gdal_create -co COMPOSITION_FILE=composition.xml out.pdf
```

Example 3: Initialize a blank GeoTIFF file from an input one

```
gdal_create -if prototype.tif output.tif
```

5.2.2.8 gdal_edit

Synopsis

```
gdal_edit [--help] [--help-general] [-ro] [-a_srs <srs_def>]
        [-a_ullr <ulx> <uly> <lrx> <lry>] [-a_ulurll <ulx> <uly> <urx> <ury> <llx> <lly>]
        [-tr <xres> <yres>] [-unsetgt] [-unsetrpc] [-a_nodata <value>] [-unsetnodata]
        [-a_coord_epoch <epoch>] [-unsetepoch]
        [-unsetstats] [-stats] [-approx_stats]
        [-setstats <min> <max> <mean> <stddev>]
        [-scale <value>] [-offset <value>] [-units <value>]
        [-colorinterp_<X>
↪{red|green|blue|alpha|gray|undefined|pan|coastal|rededge|nir|swir|mwir|lwir|...}]...
        [-gcp <pixel> <line> <easting> <northing> [<elevation>]]...
        [-unsetmd] [-oo <NAME>=<VALUE>]... [-mo <META-TAG>=<VALUE>]...
        <datasetname>
```

Description

gdal_edit can be used to edit in place various information of an existing GDAL dataset (projection, geotransform, nodata, metadata).

It works only with raster formats that support update access to existing datasets.

> **Caution**
>
> Depending on the format, older values of the updated information might still be found in the file in a "ghost" state, even if no longer accessible through the GDAL API. This is for example the case of the *GTiff -- GeoTIFF File Format* format (this is not a exhaustive list).

> **Note**
>
> gdal_edit is a Python utility, and is only available if GDAL Python bindings are available.

Tip

Equivalent in new "gdal" command line interface:

See *gdal raster edit*.

--help

Show this help message and exit

--help-general

Gives a brief usage message for the generic GDAL commandline options and exit.

-ro

Open the dataset in read-only. Might be useful for drivers refusing to use the dataset in update-mode. In which case, updated information will go into PAM `.aux.xml` files.

-a_srs <srs_def>

Defines the target coordinate system. This coordinate system will be written to the dataset. If the empty string or None is specified, then the existing coordinate system will be removed (for TIFF/GeoTIFF, might not be well supported besides that).

-a_coord_epoch <epoch>

Assign/override the coordinate epoch of the dataset, as a decimal year (e.g., 2021.3).

Added in version 3.9.

-unsetepoch

Remove the coordinate epoch of the dataset.

Added in version 3.9.

-a_ullr <ulx> <uly> <lrx> <lry>

Assign/override the georeferenced bounds of the dataset.

-a_ulurll <ulx> <uly> <urx> <ury> <llx> <lly>

Assign/override the georeferenced bounds of the dataset from three points: upper-left, upper-right and lower-left. Unlike *-a_ullr*, this also supports rotated datasets (edges not parallel to coordinate system axes).

Added in version 3.1.

-tr <xres> <yres>

Set target resolution. The values must be expressed in georeferenced units. Both must be positive values.

-unsetgt

Remove the georeference information.

-unsetrpc

Remove RPC information.

-unsetstats

Remove band statistics information.

-stats

Calculate and store band statistics.

-setstats <min> <max> <mean> <stddev>

Store user-defined values for band statistics (minimum, maximum, mean and standard deviation). If any of the values is set to None, the real statistics are calculated from the file and the ones set to None are used from the real statistics.

-approx_stats

Calculate and store approximate band statistics.

-a_nodata <value>

Assign a specified nodata value to output bands.

-unsetnodata

Remove existing nodata values.

-scale <value>

Assign a specified scale value to output bands. If a single scale value is provided it will be set for all bands. Alternatively one scale value per band can be provided, in which case the number of scale values must match the number of bands. If no scale is needed, it it recommended to set the value to 1. Scale and Offset are generally used together. For example, scale and offset might be used to store elevations in a unsigned 16bit integer file with a precision of 0.1, and starting from -100. True values would be calculated as: true_value = (pixel_value * scale) + offset

> **Note**
>
> These values can be applied using -unscale during a **gdal_translate** run.

-offset <value>

Assign a specified offset value to output bands. If a single offset value is provided it will be set for all bands. Alternatively one offset value per band can be provided, in which case the number of offset values must match the number of bands. If no offset is needed, it recommended to set the value to 0. For more see scale.

-units <value>

Assign a unit to output band(s).

Added in version 3.1.

-colorinterp_<X> {red|green|blue|alpha|gray|undefined|pan|coastal|rededge|nir|swir|mwir|lwir|...}

Change the color interpretation of band X (where X is a valid band number, starting at 1).

-gcp pixel <line> <easting> <northing> [<elevation>]

Add the indicated ground control point to the dataset. This option may be provided multiple times to provide a set of GCPs.

-unsetmd

Remove existing metadata (in the default metadata domain). Can be combined with *-mo*.

-mo <META-TAG>=<VALUE>

Passes a metadata key and value to set on the output dataset if possible. This metadata is added to the existing metadata items, unless *-unsetmd* is also specified.

-oo <NAME>=<VALUE>

Open option (format specific).

The *-a_ullr*, *-a_ulurll*, *-tr* and *-unsetgt* options are exclusive.

The *-unsetstats* and either *-stats* or *-approx_stats* options are exclusive.

Return status code

The program returns status code 0 in case of success, and non-zero in case of error (non-blocking errors emitted as warnings are considered as a successful execution).

Example

Example 1: Override the spatial bounds of a dataset and assign metadata values

```
gdal_edit -mo DATUM=WGS84 -mo PROJ=GEODETIC -a_ullr 7 47 8 46 test.ecw
```

Example 2: Assign scale and offset values to dataset

```
gdal_edit -scale 1e3 1e4 -offset 0 10 twoBand.tif
```

The values in the GeoTIFF are not changed.

5.2.2.9 gdal_fillnodata

Synopsis

```
gdal_fillnodata [--help] [--help-general] [-q] [-md <max_distance>]
           [-si <smoothing_iterations>] [-o <name>=<value> [<name>=<value> ...]]
           [-mask <filename>] [-interp {inv_dist,nearest}] [-b <band>]
           [-of <gdal_format>] [-co <name>=<value>]
           <src_file> <dst_file>
```

Description

gdal_fillnodata fills selection regions (usually nodata areas) by interpolating from valid pixels around the edges of the area.

Additional details on the algorithm are available in the *GDALFillNodata()* docs.

> **Tip**
>
> Equivalent in new "gdal" command line interface:
>
> See *gdal raster fill-nodata*.

> **Note**
>
> gdal_fillnodata is a Python utility, and is only available if GDAL Python bindings are available.

--help

Show this help message and exit

--help-general

Gives a brief usage message for the generic GDAL commandline options and exit.

-q

The script runs in quiet mode. The progress monitor is suppressed and routine messages are not displayed.

-md <max_distance>

The maximum distance (in pixels) that the algorithm will search out for values to interpolate. The default is 100 pixels.

-si <smooth_iterations>

The number of 3x3 average filter smoothing iterations to run after the interpolation to dampen artifacts. The default is zero smoothing iterations.

-o <name>=<value>

Specify a special argument to the algorithm. Currently none are supported.

-b <band>

The band to operate on, by default the first band is operated on.

-mask <filename>

Use the first band of the specified file as a validity mask (zero is invalid, non-zero is valid).

-of <format>

Select the output format. The default is *GTiff -- GeoTIFF File Format*. Use the short format name.

-interp {inv_dist,nearest}

Added in version 3.9.

By default, pixels are interpolated using an inverse distance weighting (`inv_dist`). It is also possible to choose a nearest neighbour (`nearest`) strategy.

<srcfile>

The source raster file used to identify target pixels. Only one band is used.

<dstfile>

The new file to create with the interpolated result.

Return status code

The program returns status code 0 in case of success, and non-zero in case of error (non-blocking errors emitted as warnings are considered as a successful execution).

5.2.2.10 gdal_footprint

Synopsis

```
Usage: gdal_footprint [--help] [--long-usage] [--help-general]
                      [-b <band>]... [-combine_bands VAR]
                      [[-ovr <index>]|[-srcnodata "<value>[ <value>]..."]]
                      [-t_cs VAR] [-t_srs <srs_def>] [-split_polys]
                      [-convex_hull] [-densify <value>] [-simplify <value>]
                      [-min_ring_area <value>] [-max_points <value>|unlimited]
                      [--quiet] [-oo <NAME>=<VALUE>]... [-of <output_format>]
                      [[-location_field_name <field_name>]|[-no_location]]
                      [-write_absolute_path] [-lco <NAME>=<VALUE>]...
                      [-dsco <NAME>=<VALUE>]... [-lyr_name <value>] [-overwrite]
                      <src_filename> <dst_filename>
```

Description

The **gdal_footprint** utility can be used to compute the footprint of a raster file, taking into account nodata values (or more generally the mask band attached to the raster bands), and generating polygons/multipolygons corresponding to areas where pixels are valid, and write to an output vector file.

The **nearblack** utility may be run as a pre-processing step to generate proper mask bands.

> **Tip**
>
> Equivalent in new "gdal" command line interface:
>
> See *gdal raster footprint*.

--help

Show this help message and exit

--help-general

Gives a brief usage message for the generic GDAL commandline options and exit.

-q, --quiet

Suppress progress messages and other non-error output.

-b <band>

Band(s) of interest. Between 1 and the number of bands of the raster. May be specified multiple times. If not specified, all bands are taken into account. The way multiple bands are combined is controlled by *-combine_bands*

-combine_bands `union|intersection`

Defines how the mask bands of the selected bands are combined to generate a single mask band, before being vectorized. The default value is `union`: that is a pixel is valid if it is valid at least for one of the selected bands. `intersection` means that a pixel is valid only if it is valid for all selected bands.

-ovr <index>

To specify which overview level of source file must be used, when overviews are available on the source raster. By default the full resolution level is used. The index is 0-based, that is 0 means the first overview level. This option is mutually exclusive with *-srcnodata*.

-srcnodata "<value>[<value>]..."

Set nodata values for input bands (different values can be supplied for each band). If a single value is specified, it applies to all selected bands. If more than one value is supplied, there should be as many values as the number of selected bands, and all values should be quoted to keep them together as a single operating system argument. If the option is not specified, the intrinsic mask band of each selected bands will be used.

-t_cs `pixel|georef`

Target coordinate system. By default if the input dataset is georeferenced, `georef` is implied, that is the footprint geometry will be expressed as coordinates in the CRS of the raster (or the one specified with *-t_srs*). If specifying `pixel`, the coordinates of the footprint geometry are column and line indices.

-t_srs <srs_def>

Target CRS of the output file. The <srs_def> may be any of the usual GDAL/OGR forms, complete WKT, PROJ.4, EPSG:n or a file containing the WKT. Specifying this option implies -t_cs georef The footprint is reprojected from the CRS of the source raster to the specified CRS.

-split_polys

When specified, multipolygons are split as several features each with one single polygon.

-convex_hull

When specified, the convex hull of (multi)polygons is computed.

-densify <value>

The specified value of this option is the maximum distance between 2 consecutive points of the output geometry. The unit of the distance is in pixels if *-t_cs* equals `pixel`, or otherwise in georeferenced units of the source raster. This option is applied before the reprojection implied by *-t_srs*.

-simplify <value>

The specified value of this option is the tolerance used to merge consecutive points of the output geometry using the *OGRGeometry::Simplify()* method. The unit of the distance is in pixels if *-t_cs* equals `pixel`, or otherwise in georeferenced units of the target vector dataset. This option is applied after the reprojection implied by *-t_srs*.

-min_ring_area <value>

Minimum value for the area of a ring The unit of the area is in square pixels if *-t_cs* equals `pixel`, or otherwise in georeferenced units of the target vector dataset. This option is applied after the reprojection implied by *-t_srs*

-max_points <value>|`unlimited`

Maximum number of points of each output geometry (not counting the closing point of each ring, which is always identical to the first point). The default value is 100. `unlimited` can be used to remove that limitation.

-oo <NAME>=<VALUE>

Dataset open option (format specific)

-of <ogr_format>

Select the output format. Use the short format name. Guessed from the file extension if not specified

-location_field_name <field_name>

Added in version 3.9.0.

Specifies the name of the field in the resulting vector dataset where the path of the input dataset will be stored. The default field name is "location". To prevent writing the path of the input dataset, use *-no_location*

-no_location

Added in version 3.9.0.

Turns off the writing of the path of the input dataset as a field in the output vector dataset.

-write_absolute_path

Added in version 3.9.0.

Enables writing the absolute path of the input dataset. By default, the filename is written in the location field exactly as specified on the command line.

-lco <NAME>=<VALUE>

Layer creation option (format specific)

-dsco <NAME>=<VALUE>

Dataset creation option (format specific)

-lyr_name <value>

Name of the target layer. `footprint` if not specified.

-overwrite

Overwrite the target layer if it exists.

<src_filename>

The source raster file name.

<dst_filename>

The destination vector file name. If the file and the output layer exist, the new footprint is appended to them, unless *-overwrite* is used.

Post-vectorization geometric operations are applied in the following order:

- optional splitting (*-split_polys*)
- optional densification (*-densify*)
- optional reprojection (*-t_srs*)
- optional filtering by minimum ring area (*-min_ring_area*)
- optional application of convex hull (*-convex_hull*)
- optional simplification (*-simplify*)
- limitation of number of points (*-max_points*)

Return status code

The program returns status code 0 in case of success, and non-zero in case of error (non-blocking errors emitted as warnings are considered as a successful execution).

C API

This utility is also callable from C with *GDALFootprint()*.

Examples

Example 1: Compute the footprint of a GeoTIFF file as a GeoJSON file

```
gdal_footprint -t_srs EPSG:4326 input.tif output.geojson
```

The footprint will be written using WGS84 longitude, latitude coordinates, regardless of the spatial reference system used by the input raster.

5.2.2.11 gdal_grid

Synopsis

```
gdal_grid [--help] [--help-general]
          [-ot {Byte/Int16/UInt16/UInt32/Int32/Float32/Float64/
          CInt16/CInt32/CFloat32/CFloat64}]
          [-oo <NAME>=<VALUE>]...
          [-of <format>] [-co <NAME>=<VALUE>]...
          [-zfield <field_name>] [-z_increase <increase_value>] [-z_multiply <multiply_
↪value>]
          [-a_srs <srs_def>] [-spat <xmin> <ymin> <xmax> <ymax>]
          [-clipsrc <xmin> <ymin> <xmax> <ymax>|<WKT>|<datasource>|spat_extent]
          [-clipsrcsql <sql_statement>] [-clipsrclayer <layer>]
          [-clipsrcwhere <expression>]
          [-l <layername>]... [-where <expression>] [-sql <select_statement>]
          [-txe <xmin> <xmax>] [-tye <ymin> <ymax>] [-tr <xres> <yres>] [-outsize <xsize>
↪ <ysize>]
          [-a {<algorithm>[[:<parameter1>=<value1>]...]}] [-q]
          <src_datasource> <dst_filename>
```

Description

This program creates a regular grid (raster) from the scattered data read from the OGR datasource. Input data will be interpolated to fill grid nodes with values, you can choose from various interpolation methods.

It is possible to set the *GDAL_NUM_THREADS* configuration option to parallelize the processing. The value to specify is the number of worker threads, or `ALL_CPUS` to use all the cores/CPUs of the computer.

> **Tip**
>
> Equivalent in new "gdal" command line interface:
>
> See *gdal vector grid*.

--help

Show this help message and exit

--help-general

Gives a brief usage message for the generic GDAL commandline options and exit.

-q, --quiet

Suppress progress messages and other non-error output.

-ot <type>

Force the output image bands to have a specific data type supported by the driver, which may be one of the following: `Byte`, `Int8`, `UInt16`, `Int16`, `UInt32`, `Int32`, `UInt64`, `Int64`, `Float32`, `Float64`, `CInt16`, `CInt32`, `CFloat32` or `CFloat64`.

If not set then a default type is used, which might not be supported by the relevant driver, causing a error.

-of <format>

Select the output format. If not specified, the format is guessed from the extension. Use the short format name.

-txe <xmin> <xmax>

Set georeferenced X extents of output file to be created.

-tye <ymin> <ymax>

Set georeferenced Y extents of output file to be created.

-tr <xres> <yres>

Set output file resolution (in target georeferenced units). Note that *-tr* just works in combination with a valid input from *-txe* and *-tye*

Added in version 3.2.

-outsize <xsize> <ysize>

Set the size of the output file in pixels and lines. Note that *-outsize* cannot be used with *-tr*

-a_srs <srs_def>

Override the projection for the output file. The *srs_def* may be any of the usual GDAL/OGR forms, complete WKT, PROJ.4, EPSG:n or a file containing the WKT. No reprojection is done.

-zfield <field_name>

Identifies an attribute field on the features to be used to get a Z value from. This value overrides the Z value read from the feature geometry record (naturally, if you have a Z value in the geometry, otherwise you have no choice and should specify a field name containing a Z value).

-z_increase <increase_value>

Addition to the attribute field on the features to be used to get a Z value from. The addition should be the same unit as the Z value. The result value will be Z value + Z increase value. The default value is 0.

-z_multiply <multiply_value>

This is multiplication ratio for the Z field. This can be used for a shift from e.g. feet to meters or from elevation to depth. The result value will be (Z value + Z increase value) * Z multiply value. The default value is 1.

-a {<algorithm>[[:<parameter1>=<value1>]...]}

Set the interpolation algorithm or data metric name and (optionally) its parameters. See the *Interpolation algorithms* and *Data metrics* sections for further discussion of available options.

-spat <xmin> <ymin> <xmax> <ymax>

Adds a spatial filter to select only features contained within the bounding box described by (xmin, ymin) - (xmax, ymax).

-clipsrc [<xmin> <ymin> <xmax> <ymax>]|<WKT>|<datasource>|spat_extent

Adds a spatial filter to select only features contained within the specified bounding box (expressed in source SRS), WKT geometry (POLYGON or MULTIPOLYGON), from a datasource or to the spatial extent of the *-spat* option if you use the `spat_extent` keyword. When specifying a datasource, you will generally want to use it in combination with the *-clipsrclayer*, *-clipsrcwhere* or *-clipsrcsql* options.

-clipsrcsql <sql_statement>

Select desired geometries using an SQL query instead.

-clipsrclayer <layername>

Select the named layer from the source clip datasource.

-clipsrcwhere <expression>

Restrict desired geometries based on an attribute query.

-l <layername>

Indicates the layer(s) from the datasource that will be used for input features. May be specified multiple times, but at least one layer name or a *-sql* option must be specified.

-where <expression>

An optional SQL WHERE style query expression to be applied to select features to process from the input layer(s).

-sql <select_statement>

An SQL statement to be evaluated against the datasource to produce a virtual layer of features to be processed.

-oo <NAME>=<VALUE>

Added in version 3.7.

Source dataset open option (format specific)

-co <NAME>=<VALUE>

Many formats have one or more optional creation options that can be used to control particulars about the file created. For instance, the GeoTIFF driver supports creation options to control compression, and whether the file should be tiled.

The creation options available vary by format driver, and some simple formats have no creation options at all. A list of options supported for a format can be listed with the *--format* command line option but the documentation for the format is the definitive source of information on driver creation options. See *Raster drivers* format specific documentation for legal creation options for each format.

<src_datasource>

Any OGR supported readable datasource.

`<dst_filename>`

The GDAL supported output file.

Interpolation algorithms

There are a number of interpolation algorithms to choose from.

More details about them can also be found in *GDAL Grid Tutorial*

invdist

Inverse distance to a power. This is the default algorithm. It has the following parameters:

- `power`: Weighting power (default 2.0).
- `smoothing`: Smoothing parameter (default 0.0).
- `radius1`: The first radius (X axis if rotation angle is 0) of the search ellipse. Set this parameter to zero to use the whole point array. Default is 0.0.
- `radius2`: The second radius (Y axis if rotation angle is 0) of the search ellipse. Set this parameter to zero to use the whole point array. Default is 0.0.
- `radius`: Set first and second radius (mutually exclusive with radius1 and radius2). Default is 0.0. Added in GDAL 3.6
- `angle`: Angle of search ellipse rotation in degrees (counter clockwise, default 0.0).
- `max_points`: Maximum number of data points to use. Do not search for more points than this number. This is only used if the search ellipse is set (both radii are non-zero). Zero means that all found points should be used. Default is 0.
- `min_points`: Minimum number of data points to use. If less amount of points found the grid node considered empty and will be filled with NODATA marker. This is only used if search ellipse is set (both radii are non-zero). Default is 0.
- `max_points_per_quadrant`: Maximum number of data points to use per quadrant. Default is 0. Added in GDAL 3.6. When specified, this actually uses invdistnn implementation.
- `min_points_per_quadrant`: Minimum number of data points to use per quadrant. Default is 0. Added in GDAL 3.6. When specified, this actually uses invdistnn implementation.
- `nodata`: NODATA marker to fill empty points (default 0.0).

invdistnn

Inverse distance to a power with nearest neighbor searching, ideal when max_points is used. It has following parameters:

- `power`: Weighting power (default 2.0).
- `smoothing`: Smoothing parameter (default 0.0).
- `radius`: The radius of the search circle, which should be non-zero. Default is 1.0.
- `max_points`: Maximum number of data points to use. Do not search for more points than this number. Found points will be ranked from nearest to furthest distance when weighting. Default is 12.
- `min_points`: Minimum number of data points to use. If less amount of points found the grid node is considered empty and will be filled with NODATA marker. Default is 0.
- `max_points_per_quadrant`: Maximum number of data points to use per quadrant. Default is 0. Added in GDAL 3.6. When specified, the algorithm will only take into account up to max_points_per_quadrant points for each of the right-top, left-top, right-bottom and right-top quadrant relative to the point being interpolated.

- `min_points_per_quadrant`: Minimum number of data points to use per quadrant. Default is 0. Added in GDAL 3.6. If that number is not reached, the point being interpolated will be set with the NODATA marker. When specified, the algorithm will collect at least min_points_per_quadrant points for each of the right-top, left-top, right-bottom and right-top quadrant relative to the point being interpolated.
- `nodata`: NODATA marker to fill empty points (default 0.0).

When `min_points_per_quadrant` or `max_points_per_quadrant` is specified, the search will start with the closest point to the point being interpolated from the first quadrant, then the closest point to the point being interpolated from the second quadrant, etc. up to the 4th quadrant, and will continue with the next closest point in the first quadrant, etc. until `max_points` and/or `max_points_per_quadrant` thresholds are reached.

average

Moving average algorithm. It has following parameters:

- `radius1`: The first radius (X axis if rotation angle is 0) of search ellipse. Set this parameter to zero to use whole point array. Default is 0.0.
- `radius2`: The second radius (Y axis if rotation angle is 0) of search ellipse. Set this parameter to zero to use whole point array. Default is 0.0.
- `radius`: Set first and second radius (mutually exclusive with radius1 and radius2). Default is 0.0. Added in GDAL 3.6
- `angle`: Angle of search ellipse rotation in degrees (counter clockwise, default 0.0).
- `max_points`: Maximum number of data points to use. Do not search for more points than this number. Found points will be ranked from nearest to furthest distance when weighting. Default is 0. Added in GDAL 3.6 Only taken into account if one or both of `min_points_per_quadrant` or `max_points_per_quadrant` is specified
- `min_points`: Minimum number of data points to use. If less amount of points found the grid node considered empty and will be filled with NODATA marker. Default is 0.
- `max_points_per_quadrant`: Maximum number of data points to use per quadrant. Default is 0. Added in GDAL 3.6. When specified, the algorithm will only take into account up to max_points_per_quadrant points for each of the right-top, left-top, right-bottom and right-top quadrant relative to the point being interpolated.
- `min_points_per_quadrant`: Minimum number of data points to use per quadrant. Default is 0. Added in GDAL 3.6. If that number is not reached, the point being interpolated will be set with the NODATA marker. When specified, the algorithm will collect at least min_points_per_quadrant points for each of the right-top, left-top, right-bottom and right-top quadrant relative to the point being interpolated.
- `nodata`: NODATA marker to fill empty points (default 0.0).

Note, that it is essential to set search ellipse for moving average method. It is a window that will be averaged when computing grid nodes values.

When `min_points_per_quadrant` or `max_points_per_quadrant` is specified, the search will start with the closest point to the point being interpolated from the first quadrant, then the closest point to the point being interpolated from the second quadrant, etc. up to the 4th quadrant, and will continue with the next closest point in the first quadrant, etc. until `max_points` and/or `max_points_per_quadrant` thresholds are reached.

nearest

Nearest neighbor algorithm. It has following parameters:

- `radius1`: The first radius (X axis if rotation angle is 0) of search ellipse. Set this parameter to zero to use whole point array. Default is 0.0.

- `radius2`: The second radius (Y axis if rotation angle is 0) of search ellipse. Set this parameter to zero to use whole point array. Default is 0.0.
- `radius`: Set first and second radius (mutually exclusive with radius1 and radius2). Default is 0.0. Added in GDAL 3.6
- `angle`: Angle of search ellipse rotation in degrees (counter clockwise, default 0.0).
- `nodata`: NODATA marker to fill empty points (default 0.0).

linear

Linear interpolation algorithm.

The Linear method performs linear interpolation by computing a Delaunay triangulation of the point cloud, finding in which triangle of the triangulation the point is, and by doing linear interpolation from its barycentric coordinates within the triangle. If the point is not in any triangle, depending on the radius, the algorithm will use the value of the nearest point or the nodata value.

It has following parameters:

- `radius`: In case the point to be interpolated does not fit into a triangle of the Delaunay triangulation, use that maximum distance to search a nearest neighbour, or use nodata otherwise. If set to -1, the search distance is infinite. If set to 0, nodata value will be always used. Default is -1.
- `nodata`: NODATA marker to fill empty points (default 0.0).

Data metrics

Besides the interpolation functionality **`gdal_grid`** can be used to compute some data metrics using the specified window and output grid geometry. These metrics are:

- `minimum`: Minimum value found in grid node search ellipse.
- `maximum`: Maximum value found in grid node search ellipse.
- `range`: A difference between the minimum and maximum values found in grid node search ellipse.
- `count`: A number of data points found in grid node search ellipse.
- `average_distance`: An average distance between the grid node (center of the search ellipse) and all of the data points found in grid node search ellipse.
- `average_distance_pts`: An average distance between the data points found in grid node search ellipse. The distance between each pair of points within ellipse is calculated and average of all distances is set as a grid node value.

All the metrics have the same set of options:

- `radius1`: The first radius (X axis if rotation angle is 0) of search ellipse. Set this parameter to zero to use whole point array. Default is 0.0.
- `radius2`: The second radius (Y axis if rotation angle is 0) of search ellipse. Set this parameter to zero to use whole point array. Default is 0.0.
- `radius`: Set first and second radius (mutually exclusive with radius1 and radius2). Default is 0.0. Added in GDAL 3.6
- `angle`: Angle of search ellipse rotation in degrees (counter clockwise, default 0.0).
- `min_points`: Minimum number of data points to use. If less amount of points found the grid node considered empty and will be filled with NODATA marker. This is only used if search ellipse is set (both radii are non-zero). Default is 0.

- `max_points_per_quadrant`: Maximum number of data points to use per quadrant. Default is 0. Added in GDAL 3.6. When specified, the algorithm will only take into account up to max_points_per_quadrant points for each of the right-top, left-top, right-bottom and right-top quadrant relative to the point being interpolated.
- `min_points_per_quadrant`: Minimum number of data points to use per quadrant. Default is 0. Added in GDAL 3.6. If that number is not reached, the point being interpolated will be set with the NODATA marker. When specified, the algorithm will collect at least min_points_per_quadrant points for each of the right-top, left-top, right-bottom and right-top quadrant relative to the point being interpolated.
- `nodata`: NODATA marker to fill empty points (default 0.0).

When `min_points_per_quadrant` or `max_points_per_quadrant` is specified, the search will start with the closest point to the point being interpolated from the first quadrant, then the closest point to the point being interpolated from the second quadrant, etc. up to the 4th quadrant, and will continue with the next closest point in the first quadrant, etc. until `max_points` and/or `max_points_per_quadrant` thresholds are reached.

Reading comma separated values

Often you have a text file with a list of comma separated XYZ values to work with (so called CSV file). You can easily use that kind of data source in **gdal_grid**. All you need is to create a virtual dataset header (VRT) for your CSV file and use it as an input datasource for **gdal_grid**. You can find details on the VRT format on the *VRT -- OGR Virtual Format* description page.

Here is a small example. Let's say we have a CSV file called *dem.csv* containing

```
Easting,Northing,Elevation
86943.4,891957,139.13
87124.3,892075,135.01
86962.4,892321,182.04
87077.6,891995,135.01
...
```

For the above data we will create a *dem.vrt* header with the following content:

```
<OGRVRTDataSource>
    <OGRVRTLayer name="dem">
        <SrcDataSource>dem.csv</SrcDataSource>
        <GeometryType>wkbPoint</GeometryType>
        <GeometryField encoding="PointFromColumns" x="Easting" y="Northing" z="Elevation
↪"/>
    </OGRVRTLayer>
</OGRVRTDataSource>
```

This description specifies so called 2.5D geometry with three coordinates X, Y and Z. The Z value will be used for interpolation. Now you can use *dem.vrt* with all OGR programs (start with *ogrinfo* to test that everything works fine). The datasource will contain a single layer called *"dem"* filled with point features constructed from values in the CSV file. Using this technique you can handle CSV files with more than three columns, switch columns, etc. OK, now the final step:

```
gdal_grid dem.vrt demv.tif
```

Or, if we do not wish to use a VRT file:

```
gdal_grid -l dem -oo X_POSSIBLE_NAMES=Easting \
-oo Y_POSSIBLE_NAMES=Northing -zfield Elevation dem.csv dem.tif
```

If your CSV file does not contain column headers then it can be handled in the VRT file in the following way:

```
<GeometryField encoding="PointFromColumns" x="field_1" y="field_2" z="field_3"/>
```

The *Comma Separated Value (.csv)* description page contains details on CSV format supported by GDAL/OGR.

Creating multiband files

Creating multiband files is not directly possible with gdal_grid. One might use gdal_grid multiple times to create one band per file, and then use *gdalbuildvrt* -separate and then *gdal_translate*:

```
gdal_grid ... 1.tif; gdal_grid ... 2.tif; gdal_grid ... 3.tif
gdalbuildvrt -separate 123.vrt 1.tif 2.tif 3.tif
gdal_translate 123.vrt 123.tif
```

Or just use *gdal_merge*, to combine the one-band files into a single one:

```
gdal_grid ... a.tif; gdal_grid ... b.tif; gdal_grid ... c.tif
gdal_merge -separate a.tif b.tif c.tif -o d.tif
```

Return status code

The program returns status code 0 in case of success, and non-zero in case of error (non-blocking errors emitted as warnings are considered as a successful execution).

C API

This utility is also callable from C with `GDALGrid()`.

Examples

Example 1: Create a raster from a VRT datasource using inverse distance to a power

```
gdal_grid -a invdist:power=2.0:smoothing=1.0 -txe 85000 89000 -tye 894000 890000 \
    -outsize 400 400 -of GTiff -ot Float64 -l dem dem.vrt dem.tiff
```

This example creates a raster TIFF file from the VRT datasource described in *Reading comma separated values* section using the inverse distance to a power method. Values to interpolate will be read from Z value of geometry record.

Example 2: Read values to interpolate from an attribute field

```
gdal_grid -zfield "Elevation" -a invdist:power=2.0:smoothing=1.0 -txe 85000 89000 \
    -tye 894000 890000 -outsize 400 400 -of GTiff -ot Float64 -l dem dem.vrt \
    dem.tiff --config GDAL_NUM_THREADS ALL_CPUS
```

This command does the same thing as the previous one, but reads values to interpolate from the attribute field specified with **-zfield** option instead of geometry record. So in this case X and Y coordinates are being taken from geometry and Z is being taken from the *"Elevation"* field. The `GDAL_NUM_THREADS` is also set to parallelize the computation.

5.2.2.12 gdal_merge

Synopsis

```
gdal_merge [--help] [--help-general]
               [-o <out_filename>] [-of <out_format>] [-co <NAME>=<VALUE>]...
               [-ps <pixelsize_x> <pixelsize_y>] [-tap] [-separate] [-q] [-v] [-pct]
               [-ul_lr <ulx> <uly> <lrx> <lry>] [-init "<value>[ <value>]..."]
               [-n <nodata_value>] [-a_nodata <output_nodata_value>]
               [-ot <datatype>] [-createonly] <input_file> [<input_file>]...
```

Description

This utility will automatically mosaic a set of images. All the images must be in the same coordinate system and have a matching number of bands, but they may be overlapping, and at different resolutions. In areas of overlap, the last image will be copied over earlier ones. Nodata/transparency values are considered on a band by band level, i.e. a nodata/transparent pixel on one source band will not set a nodata/transparent value on all bands for the target pixel in the resulting raster nor will it overwrite a valid pixel value.

Note

gdal_merge is a Python utility, and is only available if GDAL Python bindings are available.

Tip

Equivalent in new "gdal" command line interface:

See *gdal raster mosaic*.

--help

Show this help message and exit

--help-general

Gives a brief usage message for the generic GDAL commandline options and exit.

-o `<out_filename>`

The name of the output file, which will be created if it does not already exist (defaults to "out.tif").

-of `<format>`

Select the output format. If not specified, the format is guessed from the extension. Use the short format name.

-co `<NAME>=<VALUE>`

Many formats have one or more optional creation options that can be used to control particulars about the file created. For instance, the GeoTIFF driver supports creation options to control compression, and whether the file should be tiled.

The creation options available vary by format driver, and some simple formats have no creation options at all. A list of options supported for a format can be listed with the *--format* command line option but the documentation for the format is the definitive source of information on driver creation options. See *Raster drivers* format specific documentation for legal creation options for each format.

-ot `<type>`

Force the output image bands to have a specific data type supported by the driver, which may be one of the following: `Byte`, `Int8`, `UInt16`, `Int16`, `UInt32`, `Int32`, `UInt64`, `Int64`, `Float32`, `Float64`, `CInt16`, `CInt32`, `CFloat32` or `CFloat64`.

-ps <pixelsize_x> <pixelsize_y>

Pixel size to be used for the output file. If not specified the resolution of the first input file will be used.

-tap

(target aligned pixels) align the coordinates of the extent of the output file to the values of the -tr, such that the aligned extent includes the minimum extent. Alignment means that xmin / resx, ymin / resy, xmax / resx and ymax / resy are integer values.

-ul_lr <ulx> <uly> <lrx> <lry>

The extents of the output file. If not specified the aggregate extents of all input files will be used.

-q, -quiet

Suppress progress messages.

-v

Generate verbose output of mosaicing operations as they are done.

-separate

Place each input file into a separate band.

-pct

Grab a pseudo-color table from the first input image, and use it for the output. Merging pseudo-colored images this way assumes that all input files use the same color table.

-n <nodata_value>

Ignore pixels from files being merged in with this pixel value.

-a_nodata <output_nodata_value>

Assign a specified nodata value to output bands.

-init <"value(s)">

Pre-initialize the output image bands with these values. However, it is not marked as the nodata value in the output file. If only one value is given, the same value is used in all the bands.

-createonly

The output file is created (and potentially pre-initialized) but no input image data is copied into it.

Return status code

The program returns status code 0 in case of success, and non-zero in case of error (non-blocking errors emitted as warnings are considered as a successful execution).

Examples

Example 1: Creating an image with the pixels in all bands initialized to 255

```
gdal_merge -init 255 -o out.tif in1.tif in2.tif
```

Example 2: Creating an RGB image that shows blue in pixels with no data

```
gdal_merge -init "0 0 255" -o out.tif in1.tif in2.tif
```

The first two bands will be initialized to 0 and the third band will be initialized to 255.

Example 3: Passing a large list of files to gdal_merge

```
ls -1 *.tif > tiff_list.txt
```

A large list of files can be passed to **gdal_merge** by listing them in a text file using the command above on Linux, or:

```
dir /b /s *.tif > tiff_list.txt
```

on Windows. The text file can then be passed to **gdal_merge** using *--optfile*:

```
gdal_merge -o mosaic.tif --optfile tiff_list.txt
```

Example 4: Creating an RGB image by merging 3 different greyscale bands

Conduct "merging by stacking" with the `-separate` flag. Given three greyscale files that cover the same area, you can run:

```
gdal_merge -separate 1.tif 2.tif 3.tif -o rgb.tif
```

This maps `1.tif` to red, `2.tif` to green and `3.tif` to blue.

Example 5: Specifying overlap precedence

The last image in the input line comes out on top of the finished image stack. You might also need to use `-n` to note which value should not be copied into the destination image if it is not already defined as nodata.

```
gdal_merge -o merge.tif -n 0 image1.tif image2.tif image3.tif image4.tif
```

5.2.2.13 gdal_pansharpen

Synopsis

```
gdal_pansharpen [--help] [--help-general]
                <pan_dataset>
                <spectral_dataset>[,band=<num>] [<spectral_dataset>[,band=<num>]]...
                <out_dataset>
                [-of <format>] [-b <band>]... [-w <weight_val>]...
                [-r {nearest|bilinear|cubic|cubicspline|lanczos|average}]
                [-threads {ALL_CPUS|<number>}] [-bitdepth <val>] [-nodata <val>]
                [-spat_adjust {union|intersection|none|nonewithoutwarning}]
                [-co <NAME>=<VALUE>]... [-q]
```

Description

gdal_pansharpen performs a pan-sharpening operation. It can create a "classic" output dataset (such as GeoTIFF), or a VRT dataset describing the pan-sharpening operation.

More details can be found in the *Pansharpened VRT* section.

> **Note**
>
> gdal_pansharpen is a Python utility, and is only available if GDAL Python bindings are available.

> **Tip**
>
> Equivalent in new "gdal" command line interface:
>
> See *gdal raster pansharpen*.

--help

Show this help message and exit

--help-general

Gives a brief usage message for the generic GDAL commandline options and exit.

-of <format>

Select the output format. If not specified, the format is guessed from the extension. Use the short format name. `VRT` can also be used.

-b <band>

Select band *band* from the input spectral bands for output. Bands are numbered from 1 in the order spectral bands are specified. Multiple **-b** switches may be used. When no -b switch is used, all input spectral bands are set for output.

-w <weight_val>

Specify a weight for the computation of the pseudo panchromatic value. There must be as many -w switches as input spectral bands.

-r {nearest|bilinear|cubic|cubicspline|lanczos|average}

Select a resampling algorithm. `cubic` is the default.

-threads {ALL_CPUS|<number>}

Specify number of threads to use to do the resampling and pan-sharpening itself. Can be an integer number or `ALL_CPUS`.

-bitdepth <val>

Specify the bit depth of the panchromatic and spectral bands (e.g. 12). If not specified, the NBITS metadata item from the panchromatic band will be used if it exists.

-nodata <val>

Specify nodata value for bands. Used for the resampling and pan-sharpening computation itself. If not set, deduced from the input bands, provided they have a consistent setting.

-spat_adjust {union|intersection|none|nonewithoutwarning}

Select behavior when bands have not the same extent. See *SpatialExtentAdjustment* documentation in *Pansharpened VRT* `union` is the default.

-co <NAME>=<VALUE>

Many formats have one or more optional creation options that can be used to control particulars about the file created. For instance, the GeoTIFF driver supports creation options to control compression, and whether the file should be tiled.

The creation options available vary by format driver, and some simple formats have no creation options at all. A list of options supported for a format can be listed with the *--format* command line option but the documentation for the format is the definitive source of information on driver creation options. See *Raster drivers* format specific documentation for legal creation options for each format.

-q

Suppress progress monitor and other non-error output.

<pan_dataset>

Dataset with panchromatic band (first band will be used).

<spectral_dataset>[,band=<num>]

Dataset with one or several spectral bands. If the band option is not specified, all bands of the datasets are taken into account. Otherwise, only the specified (num)th band. The same dataset can be repeated several times.

<out_dataset>

Output dataset

Bands should be in the same projection.

Return status code

The program returns status code 0 in case of success, and non-zero in case of error (non-blocking errors emitted as warnings are considered as a successful execution).

Example

Example 1: With spectral bands in a single dataset

```
gdal_pansharpen panchro.tif multispectral.tif pansharpened_out.tif
```

Example 2: With a few spectral bands from a single dataset, reordered

```
gdal_pansharpen panchro.tif multispectral.tif,band=3 multispectral.tif,band=2␣
↪multispectral.tif,band=1 pansharpened_out.tif
```

Example 3: With spectral bands in several datasets

```
gdal_pansharpen panchro.tif band1.tif band2.tif band3.tif pansharpened_out.tif
```

Example 4: Specifying weights

```
gdal_pansharpen -w 0.7 -w 0.2 -w 0.1 panchro.tif multispectral.tif pansharpened_out.tif
```

Example 5: Specify RGB bands from a RGBNir multispectral dataset while computing the pseudo panchromatic intensity on the 4 RGBNir bands

```
gdal_pansharpen -b 1 -b 2 -b 3 panchro.tif rgbnir.tif pansharpened_out.tif
```

5.2.2.14 gdal_polygonize

Synopsis

```
gdal_polygonize [--help] [--help-general]
                    [-8] [-o <name>=<value>]... [-nomask]
                    [-mask <filename>] <raster_file> [-b <band>]
                    [-q] [-f <ogr_format>] [-lco <name>=<value>]...
                    [-overwrite] <out_file> [<layer>] [<fieldname>]
```

Description

This utility creates vector polygons for all connected regions of pixels in the raster sharing a common pixel value. Each polygon is created with an attribute indicating the pixel value of that polygon. A raster mask may also be provided to determine which pixels are eligible for processing.

The utility will create the output vector datasource if it does not already exist, otherwise it will try to append to an existing one.

The utility is based on the :*GDALPolygonize()* function which has additional details on the algorithm.

> **Note**
>
> gdal_polygonize is a Python utility, and is only available if GDAL Python bindings are available.

> **Tip**
>
> Equivalent in new "gdal" command line interface:
>
> See *gdal raster polygonize*.

--help
: Show this help message and exit

--help-general
: Gives a brief usage message for the generic GDAL commandline options and exit.

-8
: Use 8 connectedness. Default is 4 connectedness.

-nomask
: Do not use the default validity mask for the input band (such as nodata, or alpha masks).

-mask <filename>
: Use the first band of the specified file as a validity mask (zero is invalid, non-zero is valid). If not specified, the default validity mask for the input band (such as nodata, or alpha masks) will be used (unless -nomask is specified)

<raster_file>
: The source raster file from which polygons are derived.

-b <band>
: The band on <raster_file> to build the polygons from. The value can also be set to "mask", to indicate that the mask band of the first band must be used (or "mask,band_number" for the mask of a specified band)

-f <ogr_format>
: Select the output format. If not specified, the format is guessed from the extension. Use the short format name

-o <NAME>=<VALUE>
: Added in version 3.7.

  Polygonize option. See :*GDALPolygonize()* documentation.

-lco <NAME>=<VALUE>
: Added in version 3.7.

  Layer creation option (format specific)

-overwrite

Added in version 3.8.

Overwrite the output layer if it already exists.

<out_file>

The destination vector file to which the polygons will be written.

<layer>

The name of the layer created to hold the polygon features.

<fieldname>

The name of the field to create (defaults to "DN").

-q

The script runs in quiet mode. The progress monitor is suppressed and routine messages are not displayed.

Return status code

The program returns status code 0 in case of success, and non-zero in case of error (non-blocking errors emitted as warnings are considered as a successful execution).

5.2.2.15 gdal_proximity

Synopsis

```
gdal_proximity [--help] [--help-general]
                  <srcfile> <dstfile> [-srcband <n>] [-dstband <n>]
                  [-of <format>] [-co <name>=<value>]...
                  [-ot Byte/UInt16/UInt32/Float32/etc]
                  [-values <n>,<n>,<n>] [-distunits {PIXEL|GEO}]
                  [-maxdist <n>] [-nodata <n>] [-use_input_nodata {YES|NO}]
                  [-fixed-buf-val <n>]
```

Description

gdal_proximity generates a raster proximity map indicating the distance from the center of each pixel to the center of the nearest pixel identified as a target pixel. Target pixels are those in the source raster for which the raster pixel value is in the set of target pixel values.

> **Note**
>
> gdal_proximity is a Python utility, and is only available if GDAL Python bindings are available.

> **Tip**
>
> Equivalent in new "gdal" command line interface:
>
> See *gdal raster proximity*.

--help

Show this help message and exit

--help-general

Gives a brief usage message for the generic GDAL commandline options and exit.

<srcfile>

The source raster file used to identify target pixels.

<dstfile>

The destination raster file to which the proximity map will be written. It may be a pre-existing file of the same size as srcfile. If it does not exist it will be created.

-srcband <n>

Identifies the band in the source file to use (default is 1).

-dstband <n>

Identifies the band in the destination file to use (default is 1).

-of <format>

Select the output format. If not specified, the format is guessed from the extension. Use the short format name.

-co <NAME>=<VALUE>

Many formats have one or more optional creation options that can be used to control particulars about the file created. For instance, the GeoTIFF driver supports creation options to control compression, and whether the file should be tiled.

The creation options available vary by format driver, and some simple formats have no creation options at all. A list of options supported for a format can be listed with the *--format* command line option but the documentation for the format is the definitive source of information on driver creation options. See *Raster drivers* format specific documentation for legal creation options for each format.

-ot <type>

Specify a data type supported by the driver, which may be one of the following: `Byte`, `UInt16`, `Int16`, `UInt32`, `Int32`, `Float32` (default), or `Float64`.

-values <n>,<n>,<n>

A list of target pixel values in the source image to be considered target pixels. If not specified, all non-zero pixels will be considered target pixels.

-distunits {PIXEL|GEO}

Indicate whether distances generated should be in pixel or georeferenced coordinates (default PIXEL).

-maxdist <n>

The maximum distance to be generated. The nodata value will be used for pixels beyond this distance. If a nodata value is not provided, the output band will be queried for its nodata value. If the output band does not have a nodata value, then the value 65535 will be used. Distance is interpreted in pixels unless -distunits GEO is specified.

-nodata <n>

Specify a nodata value to use for the destination proximity raster.

-use_input_nodata {YES|NO}

Indicate whether nodata pixels in the input raster should be nodata in the output raster (default NO).

-fixed-buf-val <n>

Specify a value to be applied to all pixels that are within the -maxdist of target pixels (including the target pixels) instead of a distance value.

Return status code

The program returns status code 0 in case of success, and non-zero in case of error (non-blocking errors emitted as warnings are considered as a successful execution).

5.2.2.16 gdal_rasterize

Synopsis

```
Usage: gdal_rasterize [--help] [--long-usage] [--help-general]
                      [-b <band>]... [-i] [-at]

                      [-of <output_format>] [--quiet] [-oo <NAME>=<VALUE>]...
                      <src_datasource> <dst_filename>
```

Description

This program burns vector geometries (points, lines, and polygons) into the raster band(s) of a raster image. Vectors are read from OGR supported vector formats. If the output raster already exists, the affected pixels are updated in-place.

On the fly reprojection of vector data to the coordinate system of the raster data is supported.

> **Tip**
>
> Equivalent in new "gdal" command line interface:
>
> See *gdal vector rasterize*.

--help

Show this help message and exit

--help-general

Gives a brief usage message for the generic GDAL commandline options and exit.

-q, --quiet

Suppress progress messages and other non-error output.

-b <band>

The band(s) to burn values into. Multiple -b arguments may be used to burn into a list of bands. The default is to burn into band 1. Not used when creating a new raster.

-i

Invert rasterization. Burn the fixed burn value, or the burn value associated with the first feature into all parts of the image *not* inside the provided polygon.

> **Note**
>
> When the vector features contain a polygon nested within another polygon (like an island in a lake), GDAL must be built against GEOS to get correct results.

-at

Enables the ALL_TOUCHED rasterization option so that all pixels touched by lines or polygons will be updated, not just those on the line render path, or whose center point is within the polygon (behavior is unspecified when the polygon is just touching the pixel center). Defaults to disabled for normal rendering rules.

> **Note**
>
> When this option is enabled, the order of the input features (lines or polygons) can affect the results. When two features touch each other, the last one (i.e. topmost) will determine the burned pixel value at the edge. You may wish to use the *-sql* option to reorder the features (ORDER BY) to achieve a more predictable result.

-burn `<value>`

A fixed value to burn into a band for all objects. A list of *-burn* options can be supplied, one per band being written to.

-a `<attribute_name>`

Identifies an attribute field on the features to be used for a burn-in value. The value will be burned into all output bands.

-3d

Indicates that a burn value should be extracted from the "Z" values of the feature. Works with points and lines (linear interpolation along each segment). For polygons, works properly only if they are flat (same Z value for all vertices).

-add

Instead of burning a new value, this adds the new value to the existing raster. Suitable for heatmaps for instance.

-l `<layername>`

Indicates the layer(s) from the datasource that will be used for input features. May be specified multiple times, but at least one layer name or a *-sql* option must be specified (not both).

-where `<expression>`

An optional SQL WHERE style query expression to be applied to select features to burn in from the input layer(s).

-sql `<select_statement>`

An SQL statement to be evaluated against the datasource to produce a virtual layer of features to be burned in. Starting with GDAL 3.7, the `@filename` syntax can be used to indicate that the content is in the pointed filename.

> **Note**
>
> This option will be ignored if the *-l* option has been set as well.

-dialect `<dialect>`

SQL dialect. In some cases can be used to use (unoptimized) OGR SQL instead of the native SQL of an RDBMS by passing OGRSQL. The "SQLITE" dialect can also be used with any datasource.

-of <format>

Select the output format. If not specified, the format is guessed from the extension. Use the short format name.

-a_nodata <value>

Assign a specified nodata value to output bands.

-init <value>

Pre-initialize the output image bands with these values. However, it is not marked as the nodata value in the output file. If only one value is given, the same value is used in all the bands.

-a_srs <srs_def>

Override the projection for the output file. If not specified, the projection of the input vector file will be used if available. When using this option, no reprojection of features from the SRS of the input vector to the specified SRS of the output raster, so use only this option to correct an invalid source SRS. The <srs_def> may be any of the usual GDAL/OGR forms, complete WKT, PROJ.4, EPSG:n or a file containing the WKT.

-to <NAME>=<VALUE>

set a transformer option suitable to pass to *GDALCreateGenImgProjTransformer2()*. This is used when converting geometries coordinates to target raster pixel space. For example this can be used to specify RPC related transformer options.

-co <NAME>=<VALUE>

Many formats have one or more optional creation options that can be used to control particulars about the file created. For instance, the GeoTIFF driver supports creation options to control compression, and whether the file should be tiled.

The creation options available vary by format driver, and some simple formats have no creation options at all. A list of options supported for a format can be listed with the *--format* command line option but the documentation for the format is the definitive source of information on driver creation options. See *Raster drivers* format specific documentation for legal creation options for each format.

-te <xmin> <ymin> <xmax> <ymax>

Set georeferenced extents. The values must be expressed in georeferenced units. If not specified, the extent of the output file will be the extent of the vector layers.

-tr <xres> <yres>

Set target resolution. The values must be expressed in georeferenced units. Both must be positive values.

-tap

(target aligned pixels) Align the coordinates of the extent of the output file to the values of the *-tr*, such that the aligned extent includes the minimum extent. Alignment means that xmin / resx, ymin / resy, xmax / resx and ymax / resy are integer values.

-ts <width> <height>

Set output file size in pixels and lines. Note that *-ts* cannot be used with *-tr* If one of the two values is set to 0, it will be computed from the other value in order to preserve the aspect ratio.

-ot <type>

Force the output bands to be of the indicated data type. Defaults to `Float64`, unless the attribute field to burn is of type `Int64`, in which case `Int64` is used for the output raster data type if the output driver supports it.

-optim {AUTO|VECTOR|RASTER}

Force the algorithm used (results are identical). Raster mode is used in most cases and optimizes read/write operations. The vector mode is useful with a large amount of input features and optimizes CPU use, provided that the output image is tiled. Auto mode (the default) will choose the algorithm based on input and output properties.

-oo <NAME>=<VALUE>

Added in version 3.7.

Source dataset open option (format specific)

<src_datasource>

Any OGR supported readable datasource.

<dst_filename>

The GDAL supported output file. Must support update mode access. This file will be created if it does not already exist If the output raster already exists, the affected pixels are updated in-place.

The program creates a new target raster image when any of the *-of*, *-a_nodata*, *-init*, *-a_srs*, *-co*, *-te*, *-tr*, *-tap*, *-ts*, or *-ot* options are used. The resolution or size must be specified using the *-tr* or *-ts* option for all new rasters. The target raster will be overwritten if it already exists and any of these creation-related options are used.

Return status code

The program returns status code 0 in case of success, and non-zero in case of error (non-blocking errors emitted as warnings are considered as a successful execution).

C API

This utility is also callable from C with *GDALRasterize()*.

Examples

Example 1

The following would burn all polygons from `mask.shp` into the RGB TIFF file `work.tif` with the color red (RGB = 255,0,0).

```
gdal_rasterize -b 1 -b 2 -b 3 -burn 255 -burn 0 -burn 0 -l mask mask.shp work.tif
```

Example 2

The following would burn all "class A" buildings into the output elevation file, pulling the top elevation from the ROOF_H attribute.

```
gdal_rasterize -a ROOF_H -where "class='A'" -l footprints footprints.shp city_dem.tif
```

Example 3

The following would burn all polygons from `footprint.shp` into a new 1000x1000 rgb TIFF as the color red. Note that *-b* is not used; the order of the *-burn* options determines the bands of the output raster.

```
gdal_rasterize -burn 255 -burn 0 -burn 0 -ot Byte -ts 1000 1000 -l footprints footprints.
↪shp mask.tif
```

5.2.2.17 gdal_retile

Synopsis

```
gdal_retile [--help] [--help-general]
               [-v] [-co <NAME>=<VALUE>]... [-of <out_format>] [-ps <pixelWidth>
↪<pixelHeight>]
               [-overlap <val_in_pixel>]
               [-ot  {Byte/Int8/Int16/UInt16/UInt32/Int32/Float32/Float64/
                      CInt16/CInt32/CFloat32/CFloat64}]'
               [ -tileIndex <tileIndexName> [-tileIndexField <tileIndexFieldName>]]
               [-csv <fileName> [-csvDelim <delimiter>]]
               [-s_srs <srs_def>]  [-pyramidOnly]
               [-r {near|bilinear|cubic|cubicspline|lanczos}]
               -levels <numberoflevels>
               [-useDirForEachRow] [-resume]
               -targetDir <TileDirectory> <input_file> <input_file>...
```

Description

This utility will retile a set of input tile(s). All the input tile(s) must be georeferenced in the same coordinate system and have a matching number of bands. The geotransform matrix of input tiles must not contain rotation terms.

Optionally pyramid levels are generated. All pyramid levels are generated from the input tiles (not from previous levels).

It is possible to generate shape file(s) for the tiled output.

If your number of input tiles exhausts the command line buffer, use the general *--optfile* option

Note

gdal_retile is a Python utility, and is only available if GDAL Python bindings are available.

Tip

Equivalent in new "gdal" command line interface:

See *gdal raster tile* (partially equivalent).

--help

Show this help message and exit

--help-general

Gives a brief usage message for the generic GDAL commandline options and exit.

-targetDir <directory>

The directory where the tile result is created. Pyramids are stored in sub-directories numbered from 1. Created tile names have a numbering schema and contain the name of the source tiles(s)

-of <format>

Select the output format. If not specified, the format is guessed from the extension. Use the short format name.

-co <NAME>=<VALUE>

Many formats have one or more optional creation options that can be used to control particulars about the file created. For instance, the GeoTIFF driver supports creation options to control compression, and whether the file should be tiled.

The creation options available vary by format driver, and some simple formats have no creation options at all. A list of options supported for a format can be listed with the *--format* command line option but the documentation for the format is the definitive source of information on driver creation options. See *Raster drivers* format specific documentation for legal creation options for each format.

-ot <type>

Force the output image bands to have a specific data type supported by the driver, which may be one of the following: `Byte`, `Int8`, `UInt16`, `Int16`, `UInt32`, `Int32`, `UInt64`, `Int64`, `Float32`, `Float64`, `CInt16`, `CInt32`, `CFloat32` or `CFloat64`.

-ps <pixelsize_x> <pixelsize_y>

Pixel size to be used for the output file. If not specified, 256 x 256 is the default

-overlap <val_in_pixel>

Overlap in pixels between consecutive tiles. If not specified, 0 is the default

-levels <numberOfLevels>

Number of pyramids levels to build.

-v

Generate verbose output of tile operations as they are done.

-pyramidOnly

No retiling, build only the pyramids

-r <algorithm>

Resampling algorithm, default is near

-s_srs <srs_def>

Source spatial reference to use. The coordinate systems that can be passed are anything supported by the OGRSpatialReference.SetFromUserInput() call, which includes EPSG, PCS, and GCSes (i.e. EPSG:4296), PROJ.4 declarations (as above), or the name of a .prj file containing well known text. If no srs_def is given, the srs_def of the source tiles is used (if there is any). The srs_def will be propagated to created tiles (if possible) and to the optional shape file(s)

-tileIndex <tileIndexName>

The name of shape file containing the result tile(s) index

-tileIndexField <tileIndexFieldName>

The name of the attribute containing the tile name

-csv <csvFileName>

The name of the csv file containing the tile(s) georeferencing information. The file contains 5 columns: tilename,minx,maxx,miny,maxy

-csvDelim <column delimiter>

The column delimiter used in the CSV file, default value is a semicolon ";"

-useDirForEachRow

Normally the tiles of the base image are stored as described in *-targetDir*. For large images, some file systems have performance problems if the number of files in a directory is too big, causing gdal_retile not to finish in reasonable time. Using this parameter creates a different output structure. The tiles of the base image are stored in a sub-directory called 0, the pyramids in sub-directories numbered 1,2,.... Within each of these directories another level of sub-directories is created, numbered from 0...n, depending of how many tile rows are needed for each level. Finally, a directory contains only the tiles for one row for a specific level. For large images a performance improvement of a factor N could be achieved.

-resume

Resume mode. Generate only missing files.

Return status code

The program returns status code 0 in case of success, and non-zero in case of error (non-blocking errors emitted as warnings are considered as a successful execution).

5.2.2.18 gdal_sieve

Synopsis

```
gdal_sieve [--help] [--help-general]
              [-q] [-st threshold] [-4] [-8] [-o name=value]
              <srcfile> [-nomask] [-mask filename] [-of format] [<dstfile>]
```

Description

gdal_sieve removes raster polygons smaller than a provided threshold size (in pixels) and replaces them with the pixel value of the largest neighbour polygon. The result can be written back to the existing raster band, or copied into a new file.

The input dataset is read as integer data which means that floating point values are rounded to integers. Re-scaling source data may be necessary in some cases (e.g. 32-bit floating point data with min=0 and max=1).

Additional details on the algorithm are available in the *GDALSieveFilter()* docs.

Note

gdal_sieve is a Python utility, and is only available if GDAL Python bindings are available.

Tip

Equivalent in new "gdal" command line interface:

See *gdal raster sieve*.

Return status code

The program returns status code 0 in case of success, and non-zero in case of error (non-blocking errors emitted as warnings are considered as a successful execution).

5.2.2.19 gdal_translate

Synopsis

```

```

Description

The **gdal_translate** utility can be used to convert raster data between different formats, potentially performing some operations like subsetting, resampling, and rescaling pixels in the process.

Tip

Equivalent in new "gdal" command line interface:

- *gdal raster convert* for format translation.
- *gdal raster clip* for spatial subsetting.
- *gdal raster nodata-to-alpha* to add an alpha channel from nodata values.
- *gdal raster resize* for image resizing.
- *gdal raster scale* to scale pixel values.
- *gdal raster set-type* to change the band data type.

--help

Show this help message and exit

--help-general

Gives a brief usage message for the generic GDAL commandline options and exit.

-q, --quiet

Suppress progress messages and other non-error output.

-ot <type>

Force the output image bands to have a specific data type supported by the driver, which may be one of the following: `Byte`, `Int8`, `UInt16`, `Int16`, `UInt32`, `Int32`, `UInt64`, `Int64`, `Float32`, `Float64`, `CInt16`, `CInt32`, `CFloat32` or `CFloat64`.

-strict

Enable strict mode. In this mode, GDAL will fail instead of silently performing operations that may lead to loss of information, such as data type conversions that cannot be exactly preserved.

The exact behavior of this option is driver-dependent. Most raster drivers use it to enforce strict preservation of the input data type and will report an error if the requested operation cannot be performed without data loss. See *Example 5*.

-if <format>

Format/driver name to be attempted to open the input file(s). It is generally not necessary to specify it, but it can be used to skip automatic driver detection, when it fails to select the appropriate driver. This option can be repeated several times to specify several candidate drivers. Note that it does not force those drivers to open the dataset. In particular, some drivers have requirements on file extensions.

Added in version 3.2.

-of <format>

Select the output format. If not specified, the format is guessed from the extension. Use the short format name.

-b <band>

Select an input band **band** for output. Bands are numbered from 1. Multiple *-b* switches may be used to select a set of input bands to write to the output file, or to reorder bands. **band** can also be set to "mask,1" (or just "mask") to mean the mask band of the first band of the input dataset.

-mask <band>

Select an input band **band** to create output dataset mask band. Bands are numbered from 1. **band** can be set to "none" to avoid copying the global mask of the input dataset if it exists. Otherwise it is copied by default ("auto"), unless the mask is an alpha channel, or if it is explicitly used to be a regular band of the output dataset ("-b mask"). **band** can also be set to "mask,1" (or just "mask") to mean the mask band of the 1st band of the input dataset.

-expand gray|rgb|rgba

To expose a dataset with 1 band with a color table as a dataset with 3 (RGB) or 4 (RGBA) bands. Useful for output drivers such as JPEG, JPEG2000, MrSID, ECW that don't support color indexed datasets. The 'gray' value enables to expand a dataset with a color table that only contains gray levels to a gray indexed dataset.

-outsize <xsize>[%]|0 <ysize>[%]|0

Set the size of the output file. Outsize is in pixels and lines unless '%' is attached in which case it is as a fraction of the input image size. If one of the 2 values is set to 0, its value will be determined from the other one, while maintaining the aspect ratio of the source dataset.

-tr <xres> <yres>

Set target resolution. The values must be expressed in georeferenced units. Both must be positive values. This is mutually exclusive with *-outsize*, *-a_ullr*, and *-a_gt*.

-ovr {<level>|AUTO|AUTO-<n>|NONE}

Added in version 3.6.

To specify which overview level of source file must be used. The default choice, AUTO, will select the overview level whose resolution is the closest to the target resolution. Specify an integer value (0-based, i.e. 0=1st overview level) to select a particular level. Specify AUTO-n where n is an integer greater or equal to 1, to select an overview level below the AUTO one. Or specify NONE to force the base resolution to be used (can be useful if overviews

have been generated with a low quality resampling method, and a higher quality resampling method is specified with *-r*.)

When *-ovr* is specified as an integer value, and neither *-outsize* nor *-tr* is specified, the size of the overview will be used as the output size.

When *-ovr* is specified, values of *-srcwin* should be expressed as pixel offset and size of the full resolution source dataset. Similarly when using *-outsize* with percentage values, they refer to the size of the full resolution source dataset.

-r `{nearest|bilinear|cubic|cubicspline|lanczos|average|rms|mode}`

Select a resampling algorithm.

`nearest` (default) applies a nearest neighbour (simple sampling) resampler

`average` computes the average of all non-NODATA contributing pixels. Starting with GDAL 3.1, this is a weighted average taking into account properly the weight of source pixels not contributing fully to the target pixel.

`rms` computes the root mean squared / quadratic mean of all non-NODATA contributing pixels (GDAL >= 3.3)

`bilinear` applies a bilinear convolution kernel.

`cubic` applies a cubic convolution kernel.

`cubicspline` applies a B-Spline convolution kernel.

`lanczos` applies a Lanczos windowed sinc convolution kernel.

`mode` selects the value which appears most often of all the sampled points.

-scale `[<src_min> <src_max> [<dst_min> <dst_max>]]`

Rescale the input pixels values from the range **src_min** to **src_max** to the range **dst_min** to **dst_max**. If omitted the output range is from the minimum value to the maximum value allowed for integer data types (for example from 0 to 255 for Byte output) or from 0 to 1 for floating-point data types. If omitted the input range is automatically computed from the source dataset, in its whole (not just the window of interest potentially specified with *-srcwin* or *-projwin*). This may be a slow operation on a large source dataset, and if using it multiple times for several gdal_translate invocation, it might be beneficial to call `gdalinfo -stats {source_dataset}` priorly to precompute statistics, for formats that support serializing statistics computations (GeoTIFF, VRT...) Note that the values specified after *-scale* are only used to compute a scale and offset to apply to the input raster values. In particular, `src_min` and `src_max` are not used to clip input values unless *-exponent* is also specified. Instead of being clipped, source values that are outside the range of `src_min` and `src_max` will be scaled to values outside the range of `dst_min` and `dst_max`. If clipping without exponential scaling is desired, `-exponent 1` can be used. *-scale* can be repeated several times (if specified only once, it also applies to all bands of the output dataset), so as to specify per band parameters. It is also possible to use the `-scale_bn` syntax where bn is a band number (e.g. `-scale_2` for the 2nd band of the output dataset) to specify the parameters of one or several specific bands.

-exponent `<exp_val>`

Apply non-linear scaling with a power function. `exp_val` is the exponent of the power function (must be positive). This option must be used with the *-scale* option. If specified only once, *-exponent* applies to all bands of the output image. It can be repeated several times so as to specify per band parameters. It is also possible to use the `-exponent_bn` syntax where bn is a band number (e.g. `-exponent_2` for the 2nd band of the output dataset) to specify the parameters of one or several specific bands.

The scaled value `Dst` is calculated from the source value `Src` with the following formula:

$$Dst = (Dst_{max} - Dst_{min}) \times \max\left(0, \min\left(1, \left(\frac{Src - Src_{min}}{Src_{max} - Src_{min}}\right)^{exp_val}\right)\right) + Dst_{min}$$

-unscale

Apply the scale/offset metadata for the bands to convert linearly-scaled values to unscaled values. It is also often necessary to reset the output datatype with the *-ot* switch. The unscaled value is computed from the scaled raw value with the following formula:

$$unscaled_value = scaled_value * scale + offset$$

-srcwin <xoff> <yoff> <xsize> <ysize>

Selects a subwindow from the source image for copying based on pixel/line location. Pixel/line offsets (`xoff` and `yoff`) are measured from the left and top of the image. If the subwindow extends beyond the bounds of the source dataset, output pixels will be written with a value of zero, unless a NoData value is defined either in the source dataset or by *-a_nodata*. Alternatively, **gdal_translate** can issue an error in this case if so directed by options *-epo* or *-eco*.

-projwin <ulx> <uly> <lrx> <lry>

Selects a subwindow from the source image for copying (like *-srcwin*) but with the corners given in georeferenced coordinates (by default expressed in the SRS of the dataset. Can be changed with *-projwin_srs*). If the subwindow extends beyond the bounds of the source dataset, output pixels will be written with a value of zero, unless a NoData value is defined either in the source dataset or by *-a_nodata*. Alternatively, **gdal_translate** can issue an error in this case if so directed by options *-epo* or *-eco*.

> **Note**
>
> Beginning with GDAL 3.11, the extent described by *-projwin* will be transformed into the dataset SRS and used to select a subwindow. Before GDAL 3.11, only the two corner points were transformed into the dataset SRS, and these two transformed points were used to define an extent in the dataset SRS. Depending on the SRS involved, the subwindow selected in GDAL 3.11 may be substantially larger than in previous versions.

> **Note**
>
> When using nearest-neighbor resampling, the window specified by *-projwin* is expanded (rounded, for GDAL < 3.11) if necessary to match input pixel boundaries. For other resampling algorithms, the window is not modified.

-projwin_srs <srs_def>

Specifies the SRS in which to interpret the coordinates given with *-projwin*. The <srs_def> may be any of the usual GDAL/OGR forms, complete WKT, PROJ.4, EPSG:n or a file containing the WKT.

> **Warning**
>
> This does not cause reprojection of the dataset to the specified SRS.

-epo

(Error when Partially Outside) If this option is set, *-srcwin* or *-projwin* values that falls partially outside the source raster extent will be considered as an error. The default behavior is to accept such requests.

-eco

(Error when Completely Outside) Same as *-epo*, except that the criterion for erroring out is when the request falls completely outside the source raster extent.

-a_srs <srs_def>

Override the projection for the output file. Can be used with *-a_ullr* or *-a_gt* to specify the extent in this projection.

The coordinate reference systems that can be passed are anything supported by the *OGRSpatialReference::SetFromUserInput()* call, which includes EPSG Projected, Geographic or Compound CRS (i.e. EPSG:4296), a well known text (WKT) CRS definition, PROJ.4 declarations, or the name of a .prj file containing a WKT CRS definition.

> **Note**
>
> No reprojection is done.

-a_coord_epoch <epoch>

Added in version 3.4.

Assign a coordinate epoch, linked with the output SRS. Useful when the output SRS is a dynamic CRS.

-a_scale <value>

Set band scaling value. No modification of pixel values is done. Note that the *-unscale* does not take into account *-a_scale*. You may for example specify `-scale 0 1 <offset> <offset+scale>` to apply a (offset, scale) tuple, for the equivalent of the 2 steps: `gdal_translate input.tif tmp.vrt -a_scale scale -a_offset offset` followed by `gdal_translate tmp.vrt output.tif -unscale`

-a_offset <value>

Set band offset value. No modification of pixel values is done. Note that the *-unscale* does not take into account *-a_offset*. You may for example specify `-scale 0 1 <offset> <offset+scale>` to apply a (offset, scale) tuple, for the equivalent of the 2 steps: `gdal_translate input.tif tmp.vrt -a_scale scale -a_offset offset` followed by `gdal_translate tmp.vrt output.tif -unscale`

-a_ullr <ulx> <uly> <lrx> <lry>

Assign/override the georeferenced bounds of the output file. This assigns georeferenced bounds to the output file, ignoring what would have been derived from the source file. So this does not cause reprojection to the specified SRS. This is mutually exclusive with *-a_gt*

-a_gt <gt(0)> <gt(1)> <gt(2)> <gt(3)> <gt(4)> <gt(5)>

Assign/override the geotransform of the output file. This assigns the geotransform to the output file, ignoring what would have been derived from the source file. So this does not cause reprojection to the specified SRS. See *Geotransform Tutorial*. This is mutually exclusive with *-a_ullr*

Added in version 3.8.

-a_nodata <value>

Assign a specified nodata value to output bands. It can be set to `none` to avoid setting a nodata value to the output file if one exists for the source file. Note that, if the input dataset has a nodata value, this does not cause pixel values that are equal to that nodata value to be changed to the value specified with this option.

-colorinterp_X <red|green|blue|alpha|gray|undefined|pan|coastal|rededge|nir|swir|mwir|lwir|...>

Override the color interpretation of band X (where X is a valid band number, starting at 1)

-colorinterp {red|green|blue|alpha|gray|undefined|pan|coastal|rededge|nir|swir|mwir|lwir|...},...

Override the color interpretation of all specified bands. For example -colorinterp red,green,blue,alpha for a 4 band output dataset.

-mo <META-TAG>=<VALUE>

Passes a metadata key and value to set on the output dataset if possible.

-dmo DOMAIN:META-TAG=VALUE

Passes a metadata key and value in specified domain to set on the output dataset if possible.

Added in version 3.9.

-co <NAME>=<VALUE>

Many formats have one or more optional creation options that can be used to control particulars about the file created. For instance, the GeoTIFF driver supports creation options to control compression, and whether the file should be tiled.

The creation options available vary by format driver, and some simple formats have no creation options at all. A list of options supported for a format can be listed with the *--format* command line option but the documentation for the format is the definitive source of information on driver creation options. See *Raster drivers* format specific documentation for legal creation options for each format.

In addition to the driver-specific creation options, gdal_translate (and *GDALTranslate()* and *GDALCreateCopy()*) recognize the following options:

- **APPEND_SUBDATASET=[YES/NO]:** Defaults to NO.

  Can be specified to YES to avoid prior destruction of existing dataset, for drivers that support adding several subdatasets (e.g. GTIFF, NITF)

- **COPY_SRC_MDD=[AUTO/YES/NO]:** (GDAL >= 3.8) Defaults to AUTO.

  Defines if metadata domains of the source dataset should be copied to the destination dataset. In the default AUTO mode, only "safe" domains will be copied, which include the default metadata domain (some drivers may include other domains such as IMD, RPC, GEOLOCATION). When setting YES, all domains will be copied (but a few reserved ones like IMAGE_STRUCTURE or DERIVED_SUBDATASETS). Currently only recognized by the GTiff, COG, VRT, PNG and JPEG drivers.

  When setting NO, no source metadata will be copied.

- **SRC_MDD=<domain_name>:** (GDAL >= 3.8)

  Defines which source metadata domain should be copied. This option restricts the list of source metadata domains to be copied (it implies COPY_SRC_MDD=YES if it is not set). This option may be specified as many times as they are source domains. The default metadata domain is the empty string "" ("_DEFAULT_") may also be used when empty string is not practical). Currently only recognized by the GTiff, COG, VRT, PNG and JPEG drivers.

-nogcp

Do not copy the GCPs in the source dataset to the output dataset.

-gcp <pixel> <line> <easting> <northing> [<elevation>]

Add the indicated ground control point to the output dataset. This option may be provided multiple times to provide a set of GCPs.

-q

Suppress progress monitor and other non-error output.

-sds

Copy all subdatasets of this file to individual output files. Use with formats like HDF that have subdatasets.

-stats

Force (re)computation of statistics.

-norat

Do not copy source RAT into destination dataset.

-noxmp

Do not copy the XMP metadata in the source dataset to the output dataset when driver is able to copy it.

Added in version 3.2.

-oo <NAME>=<VALUE>

Dataset open option (format specific)

<src_dataset>

The source dataset name. It can be either file name, URL of data source or subdataset name for multi-dataset files.

<dst_dataset>

The destination file name.

Nodata / source validity mask handling during resampling

Masked values, either identified through a nodata value metadata set on the source band, a mask band, an alpha band will not be used during resampling (when using *-outsize* or *-tr*).

orphan

The details of how it is taken into account depends on the resampling kernel:

- for nearest resampling, for each target pixel, one of the potential contributing source pixels is selected (in an implementation specific way). Its value is used as it, be it valid or invalid.
- for bilinear, cubic, cubicspline and lanczos, for each target pixel, the weights of contributing source pixels is set to zero to ignore them when they are masked. There is an extra specificity for cubic: given that some of the weights in the kernel are negative, such strategy could lead to strong overshoot/undershoot when there is an alternance of valid and invalid pixels. Consequently, if any of the horizontal or vertical direction, if the maximum number of valid source pixels in each dimension is less than the radius of the resampling kernel, the target pixel is considered as nodata.
- for the other resampling methods, source pixels contributing to the target pixel are ignored if masked. Only the valid ones are taken into account. If there are none, the target pixel is considered as nodata.

Return status code

The program returns status code 0 in case of success, and non-zero in case of error (non-blocking errors emitted as warnings are considered as a successful execution).

C API

This utility is also callable from C with *GDALTranslate()*.

Examples

Example 1: Creating a tiled GeoTIFF

```
gdal_translate -of GTiff -co "TILED=YES" utm.tif utm_tiled.tif
```

Example 2: Creating a JPEG-compressed TIFF with internal mask from a RGBA dataset

```
gdal_translate rgba.tif withmask.tif -b 1 -b 2 -b 3 -mask 4 -co COMPRESS=JPEG \
  -co PHOTOMETRIC=YCBCR --config GDAL_TIFF_INTERNAL_MASK YES
```

Example 3: Creating a RGBA dataset from a RGB dataset with a mask

```
gdal_translate withmask.tif rgba.tif -b 1 -b 2 -b 3 -b mask
```

Example 4: Subsetting using -projwin and -outsize

```
gdal_translate -projwin -20037500 10037500 0 0 -outsize 100 100 frmt_wms_googlemaps_tms.
↪xml junk.png
```

Example 5: Use of strict mode with unsupported data type

```
$ gdal_create test.tif -bands 3 -ot Int16 -outsize 1 1
$ gdal_translate -strict test.tif test.webp
ERROR 6: WEBP driver doesn't support data type Int16.
Only UInt8 bands supported.
```

5.2.2.20 gdal_viewshed

Synopsis

```
Usage: gdal_viewshed [--help] [--long-usage] [--help-general]
                     [-of <output_format>] [-ox <value>] [-oy <value>]
                     [-oz <value>] [-vv <value>] [-iv <value>] [-ov <value>]
                     [-co <NAME>=<VALUE>]... [-a_nodata <value>] [-tz <value>]
                     [-md <value>] [-j <value>] [-cc <value>] [-b <value>]
                     [-om NORMAL|DEM|GROUND|ACCUM] [-os <value>] [-sd <value>]
                     [--quiet]
                     <src_filename> <dst_filename>
```

Description

By default the **gdal_viewshed** generates a binary visibility raster from one band of the input raster elevation model (DEM). The output raster will be of type Byte. With the -mode flag can also return a minimum visible height raster of type Float64.

> **Note**
>
> The algorithm as implemented currently will only output meaningful results if the georeferencing is in a projected coordinate reference system.

> **Tip**
>
> Equivalent in new "gdal" command line interface:

See *gdal raster viewshed*

--help

Show this help message and exit

--help-general

Gives a brief usage message for the generic GDAL commandline options and exit.

-q, --quiet

Suppress progress messages and other non-error output.

-co <NAME>=<VALUE>

Many formats have one or more optional creation options that can be used to control particulars about the file created. For instance, the GeoTIFF driver supports creation options to control compression, and whether the file should be tiled.

The creation options available vary by format driver, and some simple formats have no creation options at all. A list of options supported for a format can be listed with the *--format* command line option but the documentation for the format is the definitive source of information on driver creation options. See *Raster drivers* format specific documentation for legal creation options for each format.

-b <band>

Select an input band **band** containing the DEM data. Bands are numbered from 1. Only a single band can be used. Only the part of the raster within the specified maximum distance around the observer point is processed.

-a_nodata <value>

The value to be set for the cells in the output raster that have no data.

> **Note**
>
> Currently, no special processing of input cells at a nodata value is done (which may result in erroneous results).

-ox <value>

The X position of the observer (in SRS units). If the coordinate is outside of the raster, all space between the observer and the raster is assumed not to occlude visibility of the raster. (Not supported in cumulative mode.)

-oy <value>

The Y position of the observer (in SRS units). If the coordinate is outside of the raster, all space between the observer and the raster is assumed not to occlude visibility of the raster. (Not supported in cumulative mode.)

-oz <value>

The height of the observer above the DEM surface in the height unit of the DEM. Default: 2

-tz <value>

The height of the target above the DEM surface in the height unit of the DEM. Default: 0

-md <value>

Maximum distance from observer to compute visibility. It is also used to clamp the extent of the output raster. (Not supported in cumulative mode)

-cc <value>

Coefficient to consider the effect of the curvature and refraction. When calculating visibility between two points (i.e. Line Of Sight or Viewshed), The magnitude of this effect varies with atmospheric conditions and depends on the wavelength.

Different applications for calculating visibility use different interchangeable notation to describe this phenomena: Refraction Coefficient, Curvature Coefficient, and Sphere Diameter Factor. gdal_viewshed uses the Curvature Coefficient notation.

$$CurvCoeff = 1 - RefractionCoeff$$

Changes in air density curve the light downward causing an observer to see further and the earth to appear less curved, as if the sphere (earth) diameter is larger then it actually is. The ratio between that imaginary sphere diameter and the actual sphere diameter is given by the formula:

$$SphereDiameterFactor = 1/CurvCoeff = 1/(1 - RefractionCoeff)$$

For visible light, the standard atmospheric refraction coefficient that is generally used is 1/7. Thus the default value (since GDAL 3.4) for CurvCoeff that gdal_viewshed uses is 0.85714 (=~ 1-1/7) for Earth CRS. Starting with GDAL 3.6, for non-Earth CRS (those whole semi-major axis differs by more than 5% with the one of WGS 84), CurvCoeff default value is 1.0, to account for the no refraction use case.

The height of the DEM is corrected according to the following formula:

$$Height_{Corrected} = Height_{DEM} - CurvCoeff \frac{TargetDistance^2}{SphereDiameter}$$

Typical coefficient values are given in the table below (use Curvature Coeff value for the cc option)

Use Case	Refraction Coeff	**Curvature Coeff**	Sphere Diameter Factor
No Refraction	0	1	1
Visible Light	1/7	6/7 (=~0.85714)	7/6 (=~1.1666)
Radio Waves	0.25 ~ 0.325	0.75 ~ 0.675	1.33 ~ 1.48
Flat Earth	1	0	inf

-iv <value>

Pixel value to set for invisible areas. (Not supported in cumulative mode) Default: 0

-ov <value>

Pixel value to set for the cells that fall outside of the range specified by the observer location and the maximum distance. (Not supported in cumulative mode) Default: 0

-vv <value>

Pixel value to set for visible areas. (Not supported in cumulative mode) Default: 255

-om <output mode>

Sets what information the output contains.

Possible values: NORMAL, DEM, GROUND, ACCUM

NORMAL returns a raster of type Byte containing visible locations.

DEM and GROUND will return a raster of type Float64 containing the minimum target height for target to be visible from the DEM surface or ground level respectively. That is to say, if the minimum target height for the target to be visible at a point is `h` and the value of the input raster at that point is `E`, for `DEM`, `E + h` will be the output value. For `ground`, `h` will be output value. Flags -tz, -iv and -vv will be ignored.

Cumulative (ACCUM) mode will create an eight bit raster the same size as the input raster where each cell represents the relative observability from a grid of observer points. See the -os option.

Default NORMAL

-os <value>

Cell Spacing between observers (only supported in cumulative mode) Default: 10

-j <value>

Number of jobs to run at once. (only supported in cumulative mode) Default: 3

Return status code

The program returns status code 0 in case of success, and non-zero in case of error (non-blocking errors emitted as warnings are considered as a successful execution).

C API

Functionality of this utility can be done from C with *GDALViewshedGenerate()*.

Examples

Example 1

Screenshot of 2 combined viewshed analysis, with the yellow pixels showing the area that is visible from the both observation locations (the green dots), while the small green area is only visible from one location.

Create a viewshed raster with a radius of 500 for a person standing at location (-10147017, 5108065).

```
gdal_viewshed -md 500 -ox -10147017 -oy 5108065 source.tif destination.tif
```

Reference

5.2.2.21 gdaladdo

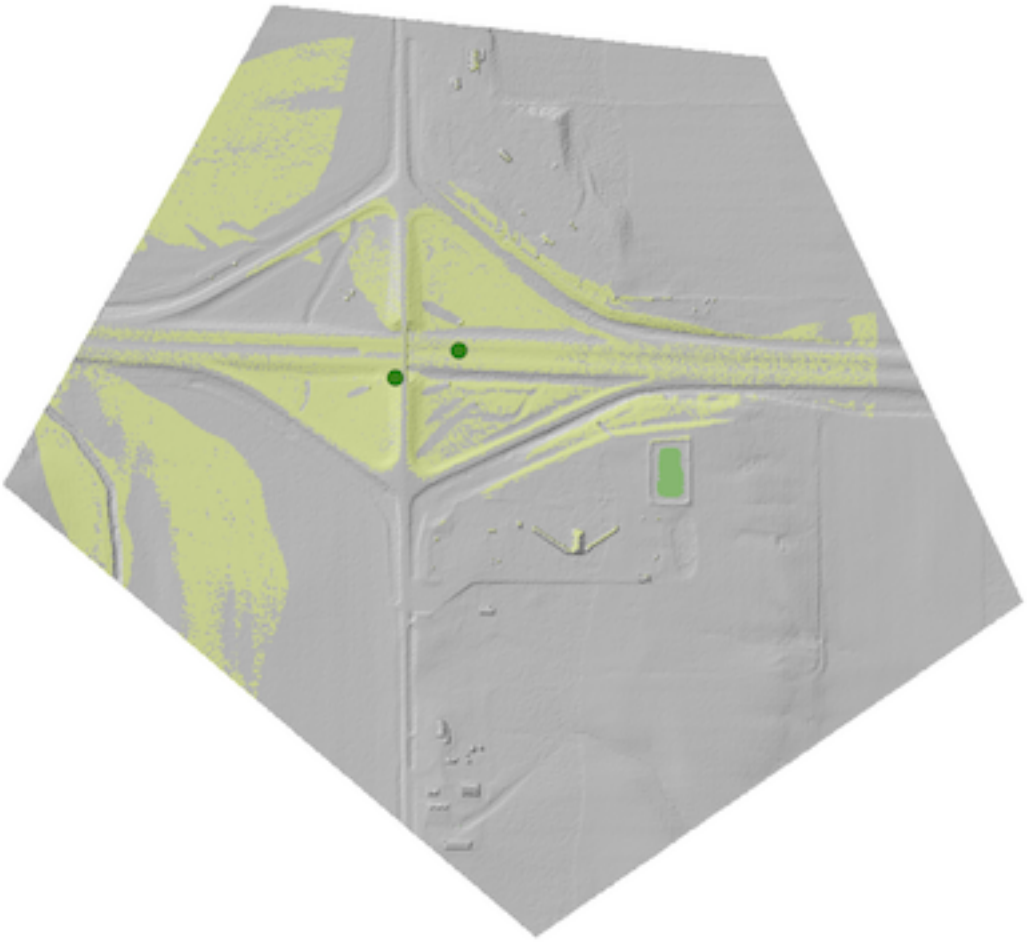
Synopsis

```
Usage: gdaladdo [--help] [--long-usage] [--help-general]
                [-r nearest|average|rms|gauss|bilinear|cubic|cubicspline|lanczos|average_
↪magphase|mode]
                [-ro] [--quiet] [-b <band>]... [-oo <NAME=VALUE>]...
                [-minsize <val>]
                [[-clean]|[--partial-refresh-from-source-timestamp]|
                [--partial-refresh-from-projwin <ulx> <uly> <lrx> <lry>]|
                [--partial-refresh-from-source-extent <filename1>[,<filenameN>]...]]
                filename [<level>]...
```

Description

The **gdaladdo** utility can be used to build or rebuild overview images for most supported file formats with one of several downsampling algorithms.

> **Tip**
>
> Equivalent in new "gdal" command line interface:
>
> See *gdal raster overview add*, *gdal raster overview delete* and *gdal raster overview refresh*.



--help

Show this help message and exit

--help-general

Gives a brief usage message for the generic GDAL commandline options and exit.

-q, --quiet

Suppress progress messages and other non-error output.

-r {nearest|average|rms|gauss|bilinear|cubic|cubicspline|lanczos|average_magphase|mode}

Select a resampling algorithm. The default is `nearest`, which is generally not appropriate if sub-pixel accuracy is desired.

Starting with GDAL 3.9, when refreshing existing TIFF overviews, the previously used method, as noted in the RESAMPLING metadata item of the overview, will be used if *-r* is not specified.

The available methods are:

`nearest` applies a nearest neighbour (simple sampling) resampler.

`average` computes the average of all non-NODATA contributing pixels. Starting with GDAL 3.1, this is a weighted average taking into account properly the weight of source pixels not contributing fully to the target pixel.

`rms` computes the root mean squared / quadratic mean of all non-NODATA contributing pixels (GDAL >= 3.3)

`gauss` applies a Gaussian kernel before computing the overview, which can lead to better results than simple averaging in e.g case of sharp edges with high contrast or noisy patterns. The advised level values should be 2, 4, 8, ... so that a 3x3 resampling Gaussian kernel is selected.

`bilinear` applies a bilinear convolution kernel.

`cubic` applies a cubic convolution kernel.

`cubicspline` applies a B-Spline convolution kernel.

`lanczos` applies a Lanczos windowed sinc convolution kernel.

`average_magphase` averages complex data in mag/phase space.

`mode` selects the value which appears most often of all the sampled points.

-b <band>

Select an input band **band** for overview generation. Band numbering starts from 1. Multiple *-b* switches may be used to select a set of input bands to generate overviews.

-ro

open the dataset in read-only mode, in order to generate external overview (for GeoTIFF especially).

-clean

remove all overviews.

-oo <NAME>=<VALUE>

Dataset open option (format specific)

-minsize <val>

Maximum width or height of the smallest overview level. Only taken into account if explicit levels are not specified. Defaults to 256.

--partial-refresh-from-source-timestamp

Added in version 3.8.

This option performs a partial refresh of existing overviews, when <filename> is a VRT file with an external overview. It checks the modification timestamp of all the sources of the VRT and regenerate the overview for areas corresponding to sources whose timestamp is more recent than the external overview of the VRT. By default all existing overview levels will be refreshed, unless explicit levels are specified. See *Example 7*.

--partial-refresh-from-projwin `<ulx> <uly> <lrx> <lry>`

Added in version 3.8.

This option performs a partial refresh of existing overviews, in the region of interest specified by georeference coordinates where <ulx> is the X value of the upper left corner, <uly> is the Y value of the upper left corner, <lrx> is the X value of the lower right corner and <lry> is the Y value of the lower right corner. By default all existing overview levels will be refreshed, unless explicit levels are specified.

--partial-refresh-from-source-extent `<filename1>[,<filenameN>]...`

Added in version 3.8.

This option performs a partial refresh of existing overviews, in the region of interest specified by one or several filenames (names separated by comma). Note that the filenames are only used to determine the regions of interest to refresh. The reference source pixels are the one of the main dataset. By default all existing overview levels will be refreshed, unless explicit levels are specified. See *Example 8*.

<filename>

The file to build overviews for (or whose overviews must be removed).

<levels>

A list of integral overview levels to build. Ignored with `-clean` option.

> Levels are no longer required to build overviews. In which case, appropriate overview power-of-two factors will be selected until the smallest overview is smaller than the value of the -minsize switch.
>
> Starting with GDAL 3.9, if there are already existing overviews, the corresponding levels will be used to refresh them if no explicit levels are specified.

gdaladdo will honour properly NODATA_VALUES tuples (special dataset metadata) so that only a given RGB triplet (in case of a RGB image) will be considered as the nodata value and not each value of the triplet independently per band.

Selecting a level value like 2 causes an overview level that is 1/2 the resolution (in each dimension) of the base layer to be computed. If the file has existing overview levels at a level selected, those levels will be recomputed and rewritten in place.

For internal GeoTIFF overviews (or external overviews in GeoTIFF format), note that -clean does not shrink the file. A later run of gdaladdo with overview levels will cause the file to be expanded, rather than reusing the space of the previously deleted overviews. If you just want to change the resampling method on a file that already has overviews computed, you don't need to clean the existing overviews.

Some format drivers do not support overviews at all. Many format drivers store overviews in a secondary file with the extension .ovr that is actually in TIFF format. By default, the GeoTIFF driver stores overviews internally to the file operated on (if it is writable), unless the -ro flag is specified.

Most drivers also support an alternate overview format using Erdas Imagine format. To trigger this use the *USE_RRD=YES* configuration option (*Example 5*). This will place the overviews in an associated .aux file suitable for direct use with Imagine or ArcGIS as well as GDAL applications. (e.g. --config USE_RRD YES)

External overviews in GeoTIFF format

External overviews created in TIFF format may be compressed using the *COMPRESS_OVERVIEW* configuration option. All compression methods, supported by the GeoTIFF driver, are available here. (e.g. `--config COMPRESS_OVERVIEW DEFLATE`). The photometric interpretation can be set with the *PHOTOMETRIC_OVERVIEW* =RGB/YCBCR/... configuration option, and the interleaving with the *INTERLEAVE_OVERVIEW* =PIXEL/BAND configuration option.

Since GDAL 3.6, *COMPRESS_OVERVIEW* and *INTERLEAVE_OVERVIEW* are honoured when creating internal overviews of TIFF files.

For JPEG compressed external and internal overviews, the JPEG quality can be set with `--config JPEG_QUALITY_OVERVIEW value`.

For WEBP compressed external and internal overviews, the WEBP quality level can be set with `--config WEBP_LEVEL_OVERVIEW value`. If not set, will default to 75.

For WEBP compressed external and internal overviews, the WEBP lossless/lossy switch can be set with `--config WEBP_LOSSLESS_OVERVIEW value`. If not set, will default to NO (lossy). Added in GDAL 3.6.0

For LERC compressed external and internal overviews, the max error threshold can be set with `--config MAX_Z_ERROR_OVERVIEW value`. If not set, will default to 0 (lossless). Added in GDAL 3.4.1

For DEFLATE or LERC_DEFLATE compressed external and internal overviews, the compression level can be set with `--config ZLEVEL_OVERVIEW value`. If not set, will default to 6. Added in GDAL 3.4.1

For ZSTD or LERC_ZSTD compressed external and internal overviews, the compression level can be set with `--config ZSTD_LEVEL_OVERVIEW value`. If not set, will default to 9. Added in GDAL 3.4.1

For JPEG-XL compressed external and internal overviews, the following settings can be set since GDAL 3.9.0:

- Whether compression should be lossless with `--config JXL_LOSSLESS_OVERVIEW YES|NO`. Default is YES
- Level of effort with `--config JXL_EFFORT_OVERVIEW value`, with value between 1(fast) and 9(flow). Default is 5
- Distance level for lossy compression with `--config JXL_DISTANCE_OVERVIEW value`, with value: 0=mathematically lossless, 1.0=visually lossless, usual range [0.5,3]. Default is 1.0. Ignored if JXL_LOSSLESS_OVERVIEW is YES
- Distance level for lossy compression of alpha channel with `--config JXL_ALPHA_DISTANCE_OVERVIEW value`, with value: 0=mathematically lossless, 1.0=visually lossless, usual range [0.5,3]. Default is the same value as JXL_DISTANCE_OVERVIEW. Ignored if JXL_LOSSLESS_OVERVIEW is YES

For LZW, ZSTD or DEFLATE compressed external overviews, the predictor value can be set with `--config PREDICTOR_OVERVIEW 1|2|3`.

To produce the smallest possible JPEG-In-TIFF overviews, you should use:

```
--config COMPRESS_OVERVIEW JPEG --config PHOTOMETRIC_OVERVIEW YCBCR --config INTERLEAVE_
↪OVERVIEW PIXEL
```

External overviews can be created in the BigTIFF format by using the *BIGTIFF_OVERVIEW* configuration option: `--config BIGTIFF_OVERVIEW {IF_NEEDED|IF_SAFER|YES|NO}`.

The default value is IF_SAFER. The behavior of this option is exactly the same as the BIGTIFF creation option documented in the GeoTIFF driver documentation.

- YES forces BigTIFF.
- NO forces classic TIFF.
- IF_NEEDED will only create a BigTIFF if it is clearly needed (uncompressed, and overviews larger than 4GB).
- IF_SAFER will create BigTIFF if the resulting file *might* exceed 4GB.

Sparse GeoTIFF overview files (that is tiles which are omitted if all their pixels are at the nodata value, when there's one, or at 0 otherwise) can be obtained with `--config SPARSE_OK_OVERVIEW ON`. Added in GDAL 3.4.1

See the documentation of the *GTiff -- GeoTIFF File Format* driver for further explanations on all those options.

Setting blocksize in Geotiff overviews

`--config GDAL_TIFF_OVR_BLOCKSIZE <size>`

Example: `--config GDAL_TIFF_OVR_BLOCKSIZE 256`

Default value is 128, or starting with GDAL 3.1, if creating overviews on a tiled GeoTIFF file, the tile size of the full resolution image. Note: without this setting, the file can have the full resolution image with a blocksize different from overviews blocksize.(e.g. full resolution image at blocksize 256, overviews at blocksize 128)

Nodata / source validity mask handling during resampling

Invalid values in source pixels, either identified through a nodata value metadata set on the source band, a mask band, an alpha band will not be used during resampling.

orphan

The details of how it is taken into account depends on the resampling kernel:

- for nearest resampling, for each target pixel, one of the potential contributing source pixels is selected (in an implementation specific way). Its value is used as it, be it valid or invalid.
- for bilinear, cubic, cubicspline and lanczos, for each target pixel, the weights of contributing source pixels is set to zero to ignore them when they are masked. There is an extra specificity for cubic: given that some of the weights in the kernel are negative, such strategy could lead to strong overshoot/undershoot when there is an alternance of valid and invalid pixels. Consequently, if any of the horizontal or vertical direction, if the maximum number of valid source pixels in each dimension is less than the radius of the resampling kernel, the target pixel is considered as nodata.
- for the other resampling methods, source pixels contributing to the target pixel are ignored if masked. Only the valid ones are taken into account. If there are none, the target pixel is considered as nodata.

Multithreading

Added in version 3.2.

The *`GDAL_NUM_THREADS`* configuration option can be set to `ALL_CPUS` or a integer value to specify the number of threads to use for overview computation.

Return status code

The program returns status code 0 in case of success, and non-zero in case of error (non-blocking errors emitted as warnings are considered as a successful execution).

C API

Functionality of this utility can be done from C with *`GDALBuildOverviews()`*.

Examples

Example 1: Create overviews, embedded in the supplied TIFF file, with automatic computation of levels

```
gdaladdo -r average abc.tif
```

Example 2: Create overviews, embedded in the supplied TIFF file

```
gdaladdo -r average abc.tif 2 4 8 16
```

Example 3: Create an external compressed GeoTIFF overview file from the ERDAS .IMG file

```
gdaladdo -ro --config COMPRESS_OVERVIEW=YES erdas.img 2 4 8 16
```

Example 4: Create an external JPEG-compressed GeoTIFF overview file from a 3-band RGB dataset

If the dataset is a writable GeoTIFF, you also need to add the *-ro* option to force the generation of external overview.

```
gdaladdo --config COMPRESS_OVERVIEW=JPEG --config PHOTOMETRIC_OVERVIEW=YCBCR
         --config INTERLEAVE_OVERVIEW=PIXEL rgb_dataset.ext 2 4 8 16
```

Example 5: Create Erdas Imagine format overviews for the indicated JPEG file

```
gdaladdo --config USE_RRD=YES airphoto.jpg 3 9 27 81
```

Example 6: Create overviews for a specific subdataset

For example, one of potentially many raster layers in a GeoPackage (the "filename" parameter must be driver prefix, filename and subdataset name, like e.g. shown by gdalinfo):

```
gdaladdo GPKG:file.gpkg:layer
```

Example 7: Refresh overviews of a VRT file

This is needed when for sources have been modified after the .vrt.ovr generation:

```
gdalbuildvrt my.vrt tile1.tif tile2.tif                        # create VRT
gdaladdo -r cubic my.vrt                                       # initial overview␣
↪generation
touch tile1.tif                                                # simulate update of␣
↪one of the source tiles
gdaladdo --partial-refresh-from-source-timestamp -r cubic my.vrt # refresh overviews
```

Example 8: Refresh overviews of a TIFF file

```
gdalwarp -overwrite tile1.tif tile2.tif mosaic.tif                        # create␣
↪mosaic
gdaladdo -r cubic mosaic.tif                                              # initial␣
↪overview generation
touch tile1.tif                                                           # simulate␣
```

(continues on next page)

(continued from previous page)

```
↪update of one of the source tiles
gdalwarp tile1.tif mosaic.tif                                          # update␣
↪mosaic
gdaladdo --partial-refresh-from-source-extent tile1.tif -r cubic mosaic.tif # refresh␣
↪overviews
```

5.2.2.22 gdalattachpct

Synopsis

```
gdalattachpct [--help] [--help-general]
                 [-of format] <palette_file> <source_file> <dest_file>
```

Description

This utility will attach a color table file from an input raster file or a color table file to another raster.

> **Note**
>
> gdalattachpct is a Python utility, and is only available if GDAL Python bindings are available.

--help
: Show this help message and exit

--help-general
: Gives a brief usage message for the generic GDAL commandline options and exit.

-of <format>
: Select the output format. If not specified, the format is guessed from the extension. Use the short format name.

<palette_file>
: Extract the color table from <palette_file>. The<palette_file> must be either a raster file in a GDAL supported format with a palette or a color file in a supported format (txt, qml, qlr).

<source_file>
: The input file.

<dest_file>
: The output RGB file that will be created.

Return status code

The program returns status code 0 in case of success, and non-zero in case of error (non-blocking errors emitted as warnings are considered as a successful execution).

5.2.2.23 gdalbuildvrt

Synopsis

```
gdalbuildvrt [--help] [--long-usage] [--help-general]
             [--quiet]
```

(continues on next page)

(continued from previous page)

```
            [[-strict]|[-non_strict]]
            [-tile_index <field_name>]
            [-resolution user|average|common|highest|lowest|same]
            [-tr <xres> <yres>] [-input_file_list <filename>]
            [[-separate]|[-pixel-function <function>]]
            [-pixel-function-arg <NAME>=<VALUE>]...
            [-allow_projection_difference] [-sd <n>] [-tap]
            [-te <xmin> <ymin> <xmax> <ymax>] [-addalpha] [-b <band>]...
            [-hidenodata] [-overwrite]

            [-oo <NAME>=<VALUE>]... [-co <NAME>=<VALUE>]...
            [-ignore_srcmaskband]
            [-nodata_max_mask_threshold <threshold>]
            <vrt_dataset_name> [<src_dataset_name>]...
```

Description

This program builds a raster *VRT (Virtual Dataset)* that is a mosaic of a list of input GDAL datasets. The list of input GDAL datasets can be specified at the end of the command line, put in a text file (one filename per line) for very long lists, or it can be a MapServer tileindex (see the *gdaltindex* utility). If using a tile index, all entries in the tile index will be added to the VRT.

> **Note**
>
> Starting with GDAL 3.9, for virtual mosaics with a very large number of source rasters (hundreds of thousands of source rasters, or more), it is advised to use the *gdaltindex* utility to generate a tile index compatible with the *GTI* driver.

> **Tip**
>
> Equivalent in new "gdal" command line interface:
>
> See *gdal raster mosaic* and *gdal raster stack*.

With `-separate`, each input goes into a separate band in the VRT dataset. Otherwise, the files are considered as source rasters of a larger mosaic and the VRT file has the same number of bands as the input files.

If one GDAL dataset is made of several subdatasets and has 0 raster bands, all the subdatasets will be added to the VRT rather than the dataset itself.

gdalbuildvrt does some checks to ensure that all files that will be put in the resulting VRT have similar characteristics: number of bands, projection, color interpretation, etc. If not, files that do not match the common characteristics will be skipped unless `-strict` is used. (This is only true in the default mode, and not when using the `-separate` option)

Starting with GDAL 3.12, a function (e.g., `min`, `mean`, `median`) can be specified (`-pixel-function`) to calculate pixel values from overlapping inputs. If no function is specified, or in earlier versions, the order of the input list is used to determine priority. Files that are listed at the end are the ones from which the content will be fetched. Note that nodata will be taken into account to potentially fetch data from lower-priority datasets, but currently, alpha channel

is not taken into account to do alpha compositing (so a source with alpha=0 appearing on top of another source will override its content). This might be changed in later versions.

--help

Show this help message and exit

--help-general

Gives a brief usage message for the generic GDAL commandline options and exit.

-q, --quiet

Suppress progress messages and other non-error output.

-tileindex <field_name>

Use the specified value as the tile index field, instead of the default value which is 'location'.

-resolution {highest|lowest|average|user|same}

In case the resolution of all input files is not the same, the *-resolution* flag enables the user to control the way the output resolution is computed.

highest will pick the smallest values of pixel dimensions within the set of source rasters.

lowest will pick the largest values of pixel dimensions within the set of source rasters.

average is the default and will compute an average of pixel dimensions within the set of source rasters.

user must be used in combination with the *-tr* option to specify the target resolution.

same (added in GDAL 3.11) checks that all source rasters have the same resolution and errors out when this is not the case.

common (added in GDAL 3.11) determines the greatest common divisor of the source pixel dimensions, e.g. 0.2 for source pixel dimensions of 0.4 and 0.6.

-tr <xres> <yres>

Set target resolution. The values must be expressed in georeferenced units. Both must be positive values. Specifying these values is of course incompatible with highest|lowest|average values for *-resolution* option.

-tap

(target aligned pixels) align the coordinates of the extent of the output file to the values of the *-tr*, such that the aligned extent includes the minimum extent. Alignment means that xmin / resx, ymin / resy, xmax / resx and ymax / resy are integer values.

-te <xmin> <ymin> <xmax> <ymax>

Set georeferenced extents of VRT file. The values must be expressed in georeferenced units. If not specified, the extent of the VRT is the minimum bounding box of the set of source rasters. Pixels within the extent of the VRT but not covered by a source raster will be read as valid pixels with a value of zero unless a NODATA value is specified using *-vrtnodata* or an alpha mask band is added with *-addalpha*.

-addalpha

Adds an alpha mask band to the VRT when the source raster have none. Mainly useful for RGB sources (or grey-level sources). The alpha band is filled on-the-fly with the value 0 in areas without any source raster, and with value 255 in areas with source raster. The effect is that a RGBA viewer will render the areas without source rasters as transparent and areas with source rasters as opaque. This option is not compatible with *-separate*.

-hidenodata

Even if any band contains nodata value, giving this option makes the VRT band not report the NoData. Useful when you want to control the background color of the dataset. By using along with the -addalpha option, you can prepare a dataset which doesn't report nodata value but is transparent in areas with no data.

-srcnodata "<value>[<value>]..."

Set nodata values for input bands (different values can be supplied for each band). If more than one value is supplied all values should be quoted to keep them together as a single operating system argument. If the option is not specified, the intrinsic nodata settings on the source datasets will be used (if they exist). The value set by this option is written in the NODATA element of each `ComplexSource` element. Use a value of `None` to ignore intrinsic nodata settings on the source datasets.

-ignore_srcmaskband

Added in version 3.3.

Starting with GDAL 3.3, if a source has a mask band (internal/external mask band, or alpha band), a `<ComplexSource>` element is created by default with a `<UseMaskBand>true</UseMaskBand>` child element, to instruct the VRT driver to use the mask band of the source to mask pixels being composited. This is a generalization of the NODATA element. When specifying the *-ignore_srcmaskband* option, the mask band of sources will not be taken into account, and in case of overlapping between sources, the last one will override previous ones in areas of overlap.

-nodata_max_mask_threshold <threshold>

Added in version 3.9.

Insert a `<NoDataFromMaskSource>` source, which replaces the value of the source with the value of *-vrtnodata* (or 0 if not specified) when the value of the mask band of the source is less or equal to the threshold. This is typically used to transform a R,G,B,A image into a R,G,B one with a NoData value.

-b <band>

Select an input <band> to be processed. Bands are numbered from 1. If input bands not set all bands will be added to the VRT. Multiple *-b* switches may be used to select a set of input bands.

-sd <n>

If the input dataset contains several subdatasets, use a subdataset with the specified number (starting from 1). This is an alternative to giving the full subdataset name as an input to the utility.

-vrtnodata "<value>[<value>]..."

Set nodata values at the VRT band level (different values can be supplied for each band). If more than one value is supplied, all values should be quoted to keep them together as a single operating system argument (*Example 4*). If the option is not specified, intrinsic nodata settings on the first dataset will be used (if they exist). The value set by this option is written in the `NoDataValue` element of each `VRTRasterBand element`. Use a value of *None* to ignore intrinsic nodata settings on the source datasets.

-separate

Place each input file into a separate band. See *Example 3*. Contrary to the default mode, it is not required that all bands have the same datatype. This option is mutually exclusive with *-pixel-function*.

Starting with GDAL 3.8, all bands of each input file are added as separate VRT bands, unless *-b* is specified to select a subset of them. Before GDAL 3.8, only the first band of each input file was placed into a new VRT band, and *-b* was ignored.

-pixel-function

Specify a function name to calculate a value from overlapping inputs. For a list of available pixel functions, see *Built-in Pixel Functions*. If no function is specified, values will be taken from the last overlapping input. This option is mutually exclusive with with *-separate*.

Added in version 3.12.

-pixel-function-arg

Specify an argument to be provided to a pixel function, in the format `<NAME>=<VALUE>`. Multiple arguments may be specified by repeating this option.

Added in version 3.12.

-allow_projection_difference

When this option is specified, the utility will create a VRT even if the input datasets do not have the same projection. Note: this does not mean that they will be reprojected. Their projection will just be ignored.

-a_srs <srs_def>

Override the projection for the output file. The <srs_def> may be any of the usual GDAL/OGR forms, complete WKT, PROJ.4, EPSG:n or a file containing the WKT. No reprojection is done.

-r {nearest|bilinear|cubic|cubicspline|lanczos|average|mode}

Select a resampling algorithm. Nearest is the default

-oo <NAME>=<VALUE>

Dataset open option (format-specific)

-co <NAME>=<VALUE>

Specify a *VRT driver creation option*.

Added in version 3.10.

-input_file_list <filename>

Specify a text file with an input filename on each line. See *Example 2*.

-q

Disable the progress bar on the console

-overwrite

Overwrite the VRT if it already exists.

-strict

Turn warnings as failures. This is mutually exclusive with *-non_strict*, the latter which is the default.

Added in version 3.4.2.

-non_strict

Skip source datasets that have issues with warnings, and continue processing. This is the default.

Added in version 3.4.2.

-write_absolute_path

Added in version 3.12.0.

Enables writing the absolute path of the input datasets. By default, input filenames are written in a relative way with respect to the VRT filename (when possible).

Examples

Example 1: Make a virtual mosaic from all TIFF files contained in a directory

```
gdalbuildvrt doq_index.vrt doq/*.tif
```

Example 2: Make a virtual mosaic from files whose name is specified in a text file

```
gdalbuildvrt -input_file_list my_list.txt doq_index.vrt
```

Example 3: Make a RGB virtual mosaic from 3 single-band input files

```
gdalbuildvrt -separate rgb.vrt red.tif green.tif blue.tif
```

Example 4: Make a virtual mosaic with blue background colour (RGB: 0 0 255)

```
gdalbuildvrt -hidenodata -vrtnodata "0 0 255" doq_index.vrt doq/*.tif
```

Return status code

The program returns status code 0 in case of success, and non-zero in case of error (non-blocking errors emitted as warnings are considered as a successful execution).

C API

This utility is also callable from C with *GDALBuildVRT()*.

5.2.2.24 gdalcompare

Synopsis

```
gdalcompare [--help] [--help-general]
               [-dumpdiffs] [-skip_binary] [-skip_overviews]
               [-skip_geolocation] [-skip_geotransform]
               [-skip_metadata] [-skip_rpc] [-skip_srs]
               [-sds] <golden_file> <new_file>
```

Description

gdalcompare compares two GDAL supported datasets and reports the differences. In addition to reporting differences to the standard output the script will also return the difference count in its exit value.

Image pixels, and various metadata are checked. There is also a byte by byte comparison done which will count as one difference. So if it is only important that the GDAL visible data is identical a difference count of 1 (the binary difference) should be considered acceptable.

> **Note**
>
> gdalcompare is a Python utility, and is only available if GDAL Python bindings are available.

--help

Show this help message and exit

--help-general

Gives a brief usage message for the generic GDAL commandline options and exit.

-dumpdiffs

Added in version 3.8.

Whether to output the difference in pixel content in a TIFF file in the current directory.

-skip_binary

Added in version 3.8.

Whether to skip exact comparison of binary content.

-skip_overviews

Added in version 3.8.

Whether to skip comparison of overviews.

-skip_geolocation

Added in version 3.8.

Whether to skip comparison of GEOLOCATION metadata domain.

-skip_geotransform

Added in version 3.8.

Whether to skip comparison of geotransform matrix.

-skip_metadata

Added in version 3.8.

Whether to skip comparison of metadata

-skip_rpc

Added in version 3.8.

Whether to skip comparison of Rational Polynomial Coefficients (RPC) metadata domain.

-skip_srs

Added in version 3.8.

Whether to skip comparison of spatial reference systems (SRS).

-sds

If this flag is passed the script will compare all subdatasets that are part of the dataset, otherwise subdatasets are ignored.

<golden_file>

The file that is considered correct, referred to as the golden file.

<new_file>

The file being compared to the golden file, referred to as the new file.

Note that the **gdalcompare** script (like all the other scripts) can also be called as a library from python code: *from osgeo_utils import gdalcompare*. The primary entry point is *gdalcompare.compare_db()* which takes a golden *gdal.Dataset* and a new *gdal.Dataset* as arguments and returns a difference count (excluding the binary comparison). The *gdalcompare.compare_sds()* entry point can be used to compare subdatasets.

Return status code

The program returns status code 0 in case of success, and non-zero in case of error (non-blocking errors emitted as warnings are considered as a successful execution).

Examples

```
gdalcompare -dumpdiffs N.tiff S.tiff; echo $?
Files differ at the binary level.
Band 1 checksum difference:
  Golden: 36694
  New:    40645
  Pixels Differing: 1509
  Maximum Pixel Difference: 255.0
  Wrote Diffs to: 1.tif
Differences Found: 2
2

gdalcompare N.tiff N.tiff; echo $?
Differences Found: 0
0
```

5.2.2.25 gdaldem

Synopsis

```
gdaldem [--help] [--help-general] <mode> <input> <output> <options>
```

From any GDAL-supported elevation raster:

Generate a shaded relief map:

```
gdaldem hillshade <input_dem> <output_hillshade>
            [-z <zfactor>] [[-s <scale>] | [-xscale <xscale> -yscale <yscale>]]
            [-az <azimuth>] [-alt <altitude>]
            [-alg ZevenbergenThorne] [-combined | -multidirectional | -igor]
            [-compute_edges] [-b <Band>] [-of <format>] [-co <NAME>=<VALUE>]... [-q]
```

Generate a slope map:

```
gdaldem slope <input_dem> <output_slope_map>
            [-p] [[-s <scale>] | [-xscale <xscale> -yscale <yscale>]]
            [-alg ZevenbergenThorne]
            [-compute_edges] [-b <band>] [-of <format>] [-co <NAME>=<VALUE>]... [-q]
```

Generate an aspect map, outputs a 32-bit float raster with pixel values from 0-360 indicating azimuth:

```
gdaldem aspect <input_dem> <output_aspect_map>
            [-trigonometric] [-zero_for_flat]
            [-alg ZevenbergenThorne]
            [-compute_edges] [-b <band>] [-of format] [-co <NAME>=<VALUE>]... [-q]
```

Generate a color relief map:

```
gdaldem color-relief <input_dem> <color_text_file> <output_color_relief_map>
             [-alpha] [-exact_color_entry | -nearest_color_entry]
             [-b <band>] [-of format] [-co <NAME>=<VALUE>]... [-q]

where color_text_file contains lines of the format "elevation_value red green blue␣
↪[alpha]". If alpha column is present it can be enabled for use with '-alpha'.
```

Generate a Terrain Ruggedness Index (TRI) map:

```
gdaldem TRI input_dem output_TRI_map
            [-alg Wilson|Riley]
            [-compute_edges] [-b Band (default=1)] [-of format] [-q]
```

Generate a Topographic Position Index (TPI) map:

```
gdaldem TPI <input_dem> <output_TPI_map>
            [-compute_edges] [-b <band>] [-of <format>] [-co <NAME>=<VALUE>]... [-q]
```

Generate a roughness map:

```
gdaldem roughness <input_dem> <output_roughness_map>
            [-compute_edges] [-b <band>] [-of <format>] [-co <NAME>=<VALUE>]... [-q]
```

Description

The **gdaldem** generates output rasters using different algorithms for terrain analysis.

In general, it assumes that x, y and z units are identical. However, for hillshade and slope computation, starting with GDAL 3.11, if none of *-scale*, *-xscale* and *-yscale* are specified, and the CRS is a geographic or projected CRS, **gdaldem** will automatically determine the appropriate ratio from the units of the CRS, as well as the potential value of the units of the raster band (as returned by *GDALRasterBand::GetUnitType()*, if it is metre, foot international or US survey foot). Note that for geographic CRS, the result for source datasets at high latitudes may be incorrect, and prior reprojection to a polar projection might be needed.

For hillshade and slope computation, if x (east-west) and y (north-south) units are identical, but z (elevation) units are different, the *-scale* option (or *-xscale* and *-yscale*) can be used to set the ratio of vertical units to horizontal. For LatLong projections near the equator, where units of latitude and units of longitude are similar, elevation (z) units can be converted to be compatible by using scale=370400 (if elevation is in feet) or scale=111120 (if elevation is in meters). For locations not near the equator, it would be best to reproject your grid using gdalwarp before using gdaldem.

<mode>

Where <mode> is one of the seven available modes:

- `hillshade`

  Generate a shaded relief map from any GDAL-supported elevation raster.

- `slope`

  Generate a slope map from any GDAL-supported elevation raster.

- `aspect`

  Generate an aspect map from any GDAL-supported elevation raster.

- `color-relief`

  Generate a color relief map from any GDAL-supported elevation raster.

- `TRI`

  Generate a map of Terrain Ruggedness Index from any GDAL-supported elevation raster.

- `TPI`

  Generate a map of Topographic Position Index from any GDAL-supported elevation raster.

- `roughness`

  Generate a map of roughness from any GDAL-supported elevation raster.

Tip

Equivalent in new "gdal" command line interface:

- *gdal raster aspect*
- *gdal raster color-map*
- *gdal raster hillshade*
- *gdal raster slope*
- *gdal raster tpi*
- *gdal raster tri*

The following general options are available:

--help
Show this help message and exit

--help-general
Gives a brief usage message for the generic GDAL commandline options and exit.

<input_dem>
The input DEM raster to be processed

<output_xxx_map>
The output raster produced

-of <format>
Select the output format.

If not specified, the format is guessed from the extension (previously was *GTiff -- GeoTIFF File Format*). Use the short format name.

-compute_edges
Do the computation at raster edges and near nodata values

-b <band>
Select an input band to be processed. Bands are numbered from 1.

-co <NAME>=<VALUE>
Many formats have one or more optional creation options that can be used to control particulars about the file created. For instance, the GeoTIFF driver supports creation options to control compression, and whether the file should be tiled.

The creation options available vary by format driver, and some simple formats have no creation options at all. A list of options supported for a format can be listed with the *--format* command line option but the documentation for the format is the definitive source of information on driver creation options. See *Raster drivers* format specific documentation for legal creation options for each format.

-q, --quiet
Suppress progress messages and other non-error output.

For all algorithms, except color-relief, a nodata value in the target dataset will be emitted if at least one pixel set to the nodata value is found in the 3x3 window centered around each source pixel. The consequence is that there will be a 1-pixel border around each image set with nodata value.

If `-compute_edges` is specified, gdaldem will compute values at image edges or if a nodata value is found in the 3x3 window, by interpolating missing values.

Modes

hillshade

This command outputs an 8-bit raster with a nice shaded relief effect. It's very useful for visualizing the terrain. You can optionally specify the azimuth and altitude of the light source, a vertical exaggeration factor and a scaling factor to account for differences between vertical and horizontal units.

The value 0 is used as the output nodata value.

The following specific options are available :

-alg `Horn|ZevenbergenThorne`

The literature suggests Zevenbergen & Thorne to be more suited to smooth landscapes, whereas Horn's formula to perform better on rougher terrain.

-z `<factor>`

Vertical exaggeration used to pre-multiply the elevations

-s `<scale>`

Ratio of vertical units to horizontal units. If the horizontal unit of the source DEM is degrees (e.g Lat/Long WGS84 projection), you can use scale=111120 if the vertical units are meters (or scale=370400 if they are in feet).

Starting with GDAL 3.11, if none of *-scale*, *-xscale* and *-yscale* are specified, and the CRS is a geographic or projected CRS, **gdaldem** will automatically determine the appropriate ratio from the units of the CRS, as well as the potential value of the units of the raster band (as returned by *GDALRasterBand::GetUnitType()*, if it is metre, foot international or US survey foot). Note that for geographic CRS, the result for source datasets at high latitudes may be incorrect, and prior reprojection to a polar projection might be needed.

The effect of this option is the same as specifying *-xscale* and *-yscale* with the same value as *-scale*. *-scale* is mutually exclusive with *-xscale* and *-yscale*

-xscale `<scale>`

Added in version 3.11.

Ratio of vertical units to horizontal X axis units. If the horizontal unit of the source DEM is degrees (e.g Lat/Long WGS84 projection), you can use scale=111120 if the vertical units are meters (or scale=370400 if they are in feet).

Starting with GDAL 3.11, if none of *-scale*, *-xscale* and *-yscale* are specified, and the CRS is a geographic or projected CRS, **gdaldem** will automatically determine the appropriate ratio from the units of the CRS, as well as the potential value of the units of the raster band (as returned by *GDALRasterBand::GetUnitType()*, if it is metre, foot international or US survey foot). Note that for geographic CRS, the result for source datasets at high latitudes may be incorrect, and prior reprojection to a polar projection might be needed.

If *-xscale* is specified, *-yscale* must also be specified.

-yscale `<scale>`

Added in version 3.11.

Ratio of vertical units to horizontal Y axis units. If the horizontal unit of the source DEM is degrees (e.g Lat/Long WGS84 projection), you can use scale=111120 if the vertical units are meters (or scale=370400 if they are in feet)

Starting with GDAL 3.11, if none of *-scale*, *-xscale* and *-yscale* are specified, and the CRS is a geographic or projected CRS, **gdaldem** will automatically determine the appropriate ratio from the units of the CRS, as well as the potential value of the units of the raster band (as returned by *GDALRasterBand::GetUnitType()*, if it is metre, foot international or US survey foot). Note that for geographic CRS, the result for source datasets at high latitudes may be incorrect, and prior reprojection to a polar projection might be needed.

If *-yscale* is specified, *-xscale* must also be specified.

-az <azimuth>

Azimuth of the light, in degrees. 0 if it comes from the top of the raster, 90 from the east, ... The default value, 315, should rarely be changed as it is the value generally used to generate shaded maps.

-alt <altitude>

Altitude of the light, in degrees. 90 if the light comes from above the DEM, 0 if it is raking light.

-combined

combined shading, a combination of slope and oblique shading.

-multidirectional

multidirectional shading, a combination of hillshading illuminated from 225 deg, 270 deg, 315 deg, and 360 deg azimuth.

-igor

shading which tries to minimize effects on other map features beneath. Can't be used with -alt option.

Added in version 3.0.

Multidirectional hillshading applies the formula of http://pubs.usgs.gov/of/1992/of92-422/of92-422.pdf.

Igor's hillshading uses formula from Maperitive http://maperitive.net/docs/Commands/GenerateReliefImageIgor.html.

slope

This command will take a DEM raster and output a 32-bit float raster with slope values. You have the option of specifying the type of slope value you want: degrees or percent slope. In cases where the horizontal units differ from the vertical units, you can also supply a scaling factor.

The value *-9999* is used as the output nodata value.

The following specific options are available :

-alg Horn|ZevenbergenThorne

The literature suggests Zevenbergen & Thorne to be more suited to smooth landscapes, whereas Horn's formula to perform better on rougher terrain.

-p

If specified, the slope will be expressed as percent slope. Otherwise, it is expressed as degrees

-s <scale>

Ratio of vertical units to horizontal units. If the horizontal unit of the source DEM is degrees (e.g Lat/Long WGS84 projection), you can use scale=111120 if the vertical units are meters (or scale=370400 if they are in feet).

Starting with GDAL 3.11, if none of *-scale*, *-xscale* and *-yscale* are specified, and the CRS is a geographic or projected CRS, **gdaldem** will automatically determine the appropriate ratio from the units of the CRS, as well as the potential value of the units of the raster band (as returned by *GDALRasterBand::GetUnitType()*, if it is metre, foot international or US survey foot). Note that for geographic CRS, the result for source datasets at high latitudes may be incorrect, and prior reprojection to a polar projection might be needed.

The effect of this option is the same as specifying *-xscale* and *-yscale* with the same value as *-scale*. *-scale* is mutually exclusive with *-xscale* and *-yscale*

-xscale <scale>

Added in version 3.11.

Ratio of vertical units to horizontal X axis units. If the horizontal unit of the source DEM is degrees (e.g Lat/Long WGS84 projection), you can use scale=111120 if the vertical units are meters (or scale=370400 if they are in feet).

Starting with GDAL 3.11, if none of *-scale*, *-xscale* and *-yscale* are specified, and the CRS is a geographic or projected CRS, **gdaldem** will automatically determine the appropriate ratio from the units of the CRS, as well as the potential value of the units of the raster band (as returned by *GDALRasterBand::GetUnitType()*, if it is metre, foot international or US survey foot). Note that for geographic CRS, the result for source datasets at high latitudes may be incorrect, and prior reprojection to a polar projection might be needed.

If *-xscale* is specified, *-yscale* must also be specified.

-yscale <scale>

Added in version 3.11.

Ratio of vertical units to horizontal Y axis units. If the horizontal unit of the source DEM is degrees (e.g Lat/Long WGS84 projection), you can use scale=111120 if the vertical units are meters (or scale=370400 if they are in feet)

Starting with GDAL 3.11, if none of *-scale*, *-xscale* and *-yscale* are specified, and the CRS is a geographic or projected CRS, **gdaldem** will automatically determine the appropriate ratio from the units of the CRS, as well as the potential value of the units of the raster band (as returned by *GDALRasterBand::GetUnitType()*, if it is metre, foot international or US survey foot). Note that for geographic CRS, the result for source datasets at high latitudes may be incorrect, and prior reprojection to a polar projection might be needed.

If *-yscale* is specified, *-xscale* must also be specified.

aspect

This command outputs a 32-bit float raster with values between 0° and 360° representing the azimuth that slopes are facing. The definition of the azimuth is such that : 0° means that the slope is facing the North, 90° it's facing the East, 180° it's facing the South and 270° it's facing the West (provided that the top of your input raster is north oriented). The aspect value -9999 is used as the nodata value to indicate undefined aspect in flat areas with slope=0.

The following specifics options are available :

-alg Horn|ZevenbergenThorne

The literature suggests Zevenbergen & Thorne to be more suited to smooth landscapes, whereas Horn's formula to perform better on rougher terrain.

-trigonometric

Return trigonometric angle instead of azimuth. Thus 0° means East, 90° North, 180° West, 270° South.

-zero_for_flat

Return 0 for flat areas with slope=0, instead of -9999.

By using those 2 options, the aspect returned by gdaldem aspect should be identical to the one of GRASS r.slope.aspect. Otherwise, it's identical to the one of Matthew Perry's `aspect.cpp` utility.

color-relief

This command outputs a 3-band (RGB) or 4-band (RGBA) raster with values are computed from the elevation and a text-based color configuration file, containing the association between various elevation values and the corresponding wished color. By default, the colors between the given elevation values are blended smoothly and the result is a nice colorized DEM. The -exact_color_entry or -nearest_color_entry options can be used to avoid that linear interpolation for values that don't match an index of the color configuration file.

The following specifics options are available :

color_text_file

Text-based color configuration file

-alpha

Add an alpha channel to the output raster

-exact_color_entry

Use strict matching when searching in the color configuration file. If none matching color entry is found, the "0,0,0,0" RGBA quadruplet will be used

-nearest_color_entry

Use the RGBA quadruplet corresponding to the closest entry in the color configuration file.

The color-relief mode is the only mode that supports VRT as output format. In that case, it will translate the color configuration file into appropriate LUT elements. Note that elevations specified as percentage will be translated as absolute values, which must be taken into account when the statistics of the source raster differ from the one that was used when building the VRT.

The text-based color configuration file generally contains 4 columns per line: the elevation value and the corresponding Red, Green, Blue component (between 0 and 255). The elevation value can be any floating point value, or the nv keyword for the nodata value. The elevation can also be expressed as a percentage: 0% being the minimum value found in the raster, 100% the maximum value.

An extra column can be optionally added for the alpha component. If it is not specified, full opacity (255) is assumed.

Various field separators are accepted: comma, tabulation, spaces, ':'.

Common colors used by GRASS can also be specified by using their name, instead of the RGB triplet. The supported list is: white, black, red, green, blue, yellow, magenta, cyan, aqua, grey/gray, orange, brown, purple/violet and indigo.

GMT `.cpt` palette files are also supported (COLOR_MODEL = RGB only).

Note: the syntax of the color configuration file is derived from the one supported by GRASS r.colors utility. ESRI HDR color table files (.clr) also match that syntax. The alpha component and the support of tab and comma as separators are GDAL specific extensions.

For example:

```
3500   white
2500   235:220:175
50%   190 185 135
700    240 250 150
0      50  180  50
nv     0   0   0   0
```

To implement a "round to the floor value" mode, the elevation value can be duplicate with a new value being slightly above the threshold. For example to have red in [0,10], green in]10,20] and blue in]20,30]:

```
0       red
10      red
10.001  green
20      green
20.001  blue
30      blue
```

TRI

This command outputs a single-band raster with values computed from the elevation. *TRI* stands for Terrain Ruggedness Index, which measures the difference between a central pixel and its surrounding cells.

The value -9999 is used as the output nodata value.

The following option is available:

-alg `Wilson|Riley`

Starting with GDAL 3.3, the Riley algorithm (see Riley, S.J., De Gloria, S.D., Elliot, R. (1999): A Terrain Ruggedness that Quantifies Topographic Heterogeneity. Intermountain Journal of Science, Vol.5, No.1-4, pp.23-27) is available and the new default value. This algorithm uses the square root of the sum of the square of the difference between a central pixel and its surrounding cells. This is recommended for terrestrial use cases.

The Wilson (see Wilson et al 2007, Marine Geodesy 30:3-35) algorithm uses the mean difference between a central pixel and its surrounding cells. This is recommended for bathymetric use cases.

TPI

This command outputs a single-band raster with values computed from the elevation. *TPI* stands for Topographic Position Index, which is defined as the difference between a central pixel and the mean of its surrounding cells (see Wilson et al 2007, Marine Geodesy 30:3-35).

The value -9999 is used as the output nodata value.

There are no specific options.

roughness

This command outputs a single-band raster with values computed from the elevation. Roughness is the largest inter-cell difference of a central pixel and its surrounding cell, as defined in Wilson et al (2007, Marine Geodesy 30:3-35).

The value -9999 is used as the output nodata value.

There are no specific options.

Return status code

The program returns status code 0 in case of success, and non-zero in case of error (non-blocking errors emitted as warnings are considered as a successful execution).

C API

This utility is also callable from C with *`GDALDEMProcessing()`*.

5.2.2.26 gdalenhance

Synopsis

```
gdalenhance [--help-general]
            [-of format] [-co "NAME=VALUE"]*
            [-ot {Byte/Int16/UInt16/UInt32/Int32/Float32/Float64/
                    CInt16/CInt32/CFloat32/CFloat64}]
            [-equalize]
            [-config filename]
            <src_raster> [<dst_raster>]
```

Description

The **gdalenhance** utility enhances the contrast of raster images using histogram equalization. It can either generate a LUT (look-up-table) that can later be applied to enhance contrast, or it can write the enhanced image directly.

Fig. 17: Original image.

--help

Show this help message and exit

--help-general

Gives a brief usage message for the generic GDAL commandline options and exit.

-of format

Select the output format. The default is GeoTIFF (GTiff).

VRT output is not supported.

-co <NAME>=<VALUE>

Many formats have one or more optional creation options that can be used to control particulars about the file

Fig. 18: Image after histogram equalization using **gdalenhance**.

created. For instance, the GeoTIFF driver supports creation options to control compression, and whether the file should be tiled.

The creation options available vary by format driver, and some simple formats have no creation options at all. A list of options supported for a format can be listed with the *--format* command line option but the documentation for the format is the definitive source of information on driver creation options. See *Raster drivers* format specific documentation for legal creation options for each format.

-ot <type>

Force the output image bands to have a specific data type supported by the driver, which may be one of the following: `Byte`, `Int8`, `UInt16`, `Int16`, `UInt32`, `Int32`, `UInt64`, `Int64`, `Float32`, `Float64`, `CInt16`, `CInt32`, `CFloat32` or `CFloat64`.

-equalize

Get source image histogram and compute equalization LUTs from it.

-config <filename>

Apply a specified LUT to enhance the contrast of the image. The number of lines in the LUT file should be equal to the number of bands of the images. Example of LUT file:

```
1:Band -0.5:ScaleMin 255.5:ScaleMax 0 0 8 16 16 17 17 17 17 18 18 18 18 18 18 19 19␣
↪19 19 20 20 20 21 21 21 22 22 22 23 23 24 24 25 25 26 27 27 28 29 30 30 31 32 33␣
↪34 35 36 37 38 39 40 42 43 44 46 47 48 50 51 53 55 56 58 60 62 63 65 67 69 71 73␣

```

Return status code

The program returns status code 0 in case of success, and non-zero in case of error (non-blocking errors emitted as warnings are considered as a successful execution).

Examples

Example 1: Apply equalization histogram to enhance the contrast of the image

```
gdalenhance -equalize rgb.tif rgb_equalize_enhance.tif
```

Example 2: Write an equalization LUT to the console

```
gdalenhance -equalize rgb.tif
```

Example 3: Apply a custom LUT (look up-table) to enhance the contrast of the image

```
gdalenhance -config enhance_config rgb.tif rgb_custom_enhance.tif
```

5.2.2.27 gdalinfo

Synopsis

```
Usage: gdalinfo [--help] [--long-usage] [--help-general]
                [-json] [-mm]
                [[-stats]|[-approx_stats]]
                [-hist]
                [-nogcp] [-nomd] [-norat] [-noct] [-nofl] [-nonodata] [-nomask]
                [-checksum] [-listmdd] [-proj4]
                [-wkt_format <WKT1|WKT1_ESRI|WKT2|WKT2_2015|WKT2_2018|WKT2_2019>]
```

(continues on next page)

(continued from previous page)

```
                [-sd <n>] [-oo <NAME>=<VALUE>]... [-if <format>]...
                [-mdd <domain>|all]
                <dataset_name>
```

Description

gdalinfo program lists various information about a GDAL supported raster dataset.

The following command line parameters can appear in any order

> **Tip**
>
> Equivalent in new "gdal" command line interface:
>
> See *gdal raster info*.

--help

Show this help message and exit

--help-general

Gives a brief usage message for the generic GDAL commandline options and exit.

-json

Display the output in json format. Since GDAL 3.6, this includes key-value pairs useful for building a STAC item , including statistics and histograms if `-stats` or `-hist` flags are passed, respectively.

-mm

Force computation of the actual min/max values for each band in the dataset.

-stats

Read and display image statistics. Force computation if no statistics are stored in an image.

-approx_stats

Read and display image statistics. Force computation if no statistics are stored in an image. However, they may be computed based on overviews or a subset of all tiles. Useful if you are in a hurry and don't need precise stats.

-hist

Report histogram information for all bands.

-nogcp

Suppress ground control points list printing. It may be useful for datasets with huge amount of GCPs, such as L1B AVHRR or HDF4 MODIS which contain thousands of them.

-nomd

Suppress metadata printing. Some datasets may contain a lot of metadata strings.

-norat

Suppress printing of raster attribute table.

-noct

Suppress printing of color table.

-nonodata

Added in version 3.10.

Suppress nodata printing. Implies *-nomask*.

Can be useful for example when querying a remove GRIB2 dataset that has an index .idx side-car file, together with *-nomd*

-nomask

Added in version 3.10.

Suppress band mask printing. Is implied if *-nonodata* is specified.

-checksum

Force computation of the checksum for each band in the dataset.

-listmdd

List all metadata domains available for the dataset.

-mdd `<domain>|all`

adds metadata using:

`domain` Report metadata for the specified domain.

`all` Report metadata for all domains.

-nofl

Only display the first file of the file list.

-wkt_format `WKT1|WKT1_ESRI|WKT2|WKT2_2015|WKT2_2018|WKT2_2019`

WKT format used to display the SRS. Currently the supported values are:

`WKT1`

`WKT1_ESRI`

`WKT2` (latest WKT version, currently *WKT2_2019*)

`WKT2_2015`

`WKT2_2018` (deprecated)

`WKT2_2019`

Added in version 3.0.0.

-sd `<n>`

If the input dataset contains several subdatasets read and display a subdataset with specified `n` number (starting from 1). This is an alternative of giving the full subdataset name.

-proj4

Report a PROJ.4 string corresponding to the file's coordinate system.

-oo `<NAME>=<VALUE>`

Dataset open option (format specific).

-if `<format>`

Format/driver name to be attempted to open the input file(s). It is generally not necessary to specify it, but it can be used to skip automatic driver detection, when it fails to select the appropriate driver. This option can be repeated several times to specify several candidate drivers. Note that it does not force those drivers to open the dataset. In particular, some drivers have requirements on file extensions.

Added in version 3.2.

The gdalinfo will report all of the following (if known):

- The format driver used to access the file.
- Raster size (in pixels and lines).
- The coordinate system for the file (in OGC WKT).
- The geotransform associated with the file (rotational coefficients are currently not reported).
- Corner coordinates in georeferenced, and if possible lat/long based on the full geotransform (but not GCPs).
- Ground control points.
- File wide (including subdatasets) metadata.
- Band data types.
- Band color interpretations.
- Band block size.
- Band descriptions.
- Band min/max values (internally known and possibly computed).
- Band checksum (if computation asked).
- Band NODATA value.
- Band overview resolutions available.
- Band unit type (i.e.. "meters" or "feet" for elevation bands).
- Band pseudo-color tables.

Return status code

The program returns status code 0 in case of success, and non-zero in case of error (non-blocking errors emitted as warnings are considered as a successful execution).

C API

This utility is also callable from C with *GDALInfo()*.

Examples

Example 1: Default output format

```
$ gdalinfo utmsmall.tif
Driver: GTiff/GeoTIFF
Files: utmsmall.tif
Size is 100, 100
Coordinate System is:
PROJCRS["NAD27 / UTM zone 11N",
    BASEGEOGCRS["NAD27",
        DATUM["North American Datum 1927",
            ELLIPSOID["Clarke 1866",6378206.4,294.978698213898,
                LENGTHUNIT["metre",1]]],
        PRIMEM["Greenwich",0,
            ANGLEUNIT["degree",0.0174532925199433]],
        ID["EPSG",4267]],
```

(continues on next page)

(continued from previous page)

```
    CONVERSION["Transverse Mercator",
        METHOD["Transverse Mercator",
            ID["EPSG",9807]],
        PARAMETER["Latitude of natural origin",0,
            ANGLEUNIT["degree",0.0174532925199433],
            ID["EPSG",8801]],
        PARAMETER["Longitude of natural origin",-117,
            ANGLEUNIT["degree",0.0174532925199433],
            ID["EPSG",8802]],
        PARAMETER["Scale factor at natural origin",0.9996,
            SCALEUNIT["unity",1],
            ID["EPSG",8805]],
        PARAMETER["False easting",500000,
            LENGTHUNIT["metre",1],
            ID["EPSG",8806]],
        PARAMETER["False northing",0,
            LENGTHUNIT["metre",1],
            ID["EPSG",8807]]],
    CS[Cartesian,2],
        AXIS["easting",east,
            ORDER[1],
            LENGTHUNIT["metre",1]],
        AXIS["northing",north,
            ORDER[2],
            LENGTHUNIT["metre",1]],
    ID["EPSG",26711]]
Data axis to CRS axis mapping: 1,2
Origin = (440720.000000000000000,3751320.000000000000000)
Pixel Size = (60.000000000000000,-60.000000000000000)
Metadata:
  AREA_OR_POINT=Area
Image Structure Metadata:
  INTERLEAVE=BAND
Corner Coordinates:
Upper Left  (  440720.000, 3751320.000) (117d38'28.21"W, 33d54' 8.47"N)
Lower Left  (  440720.000, 3745320.000) (117d38'26.75"W, 33d50'53.66"N)

Lower Right (  446720.000, 3745320.000) (117d34'33.28"W, 33d50'54.82"N)
Center      (  443720.000, 3748320.000) (117d36'30.71"W, 33d52'31.66"N)
Band 1 Block=100x81 Type=Byte, ColorInterp=Gray
```

Example 2: JSON output

For corner coordinates formatted as decimal degree instead of the above degree, minute, second, inspect the `wgs84Extent` member of `gdalinfo -json`:

Example of JSON output with `gdalinfo -json utmsmall.tif`:

```
{
  "description":"utmsmall.tif",
  "driverShortName":"GTiff",
  "driverLongName":"GeoTIFF",
```

5.2.2.28 gdallocationinfo

Synopsis

```
Usage: gdallocationinfo [--help] [--long-usage] [--help-general]
                        [-xml] [-lifonly] [-valonly] [-E] [-field_sep <sep>]
                        [-ignore_extra_input] [-b <band>]...
                        [-overview <overview_level>]
                        [-r nearest|bilinear|cubic|cubicspline]
                        [[-l_srs <srs_def>]|[-geoloc]|[-wgs84]]
                        [-oo <NAME>=<VALUE>]...
                        <srcfile> <x> <y>
```

Description

The **gdallocationinfo** utility provide a mechanism to query information about a pixel given its location in one of a variety of coordinate systems. Several reporting options are provided.

> **Tip**
>
> Equivalent in new "gdal" command line interface:
>
> See *gdal raster pixel-info*.

--help

Show this help message and exit

--help-general

Gives a brief usage message for the generic GDAL commandline options and exit.

-xml

The output report will be XML formatted for convenient post processing. (*Example 2*).

-lifonly

The only output is filenames production from the LocationInfo request against the database (i.e. for identifying impacted file from VRT).

-valonly

The only output is the pixel values of the selected pixel on each of the selected bands. By default, the value of each band is output on a separate line, unless *-field_sep* is specified.

-b <band>

Selects a band to query. Multiple bands can be listed. By default all bands are queried.

-r {nearest|bilinear|cubic|cubicspline}

Added in version 3.10.

Select a sampling algorithm. The default is `nearest`.

The available methods are:

`nearest` applies a nearest neighbour.

`bilinear` applies a bilinear convolution kernel.

`cubic` applies a cubic convolution kernel.

`cubicspline` applies a B-Spline convolution kernel.

-overview <overview_level>

Query the (overview_level)th overview (overview_level=1 is the 1st overview), instead of the base band. Note that the x,y location (if the coordinate system is pixel/line) must still be given with respect to the base band.

-l_srs <srs_def>

The coordinate system of the input x, y location.

-geoloc

Indicates input x,y points are in the georeferencing system of the image.

-wgs84

Indicates input x,y points are WGS84 long, lat.

-oo <NAME>=<VALUE>

Dataset open option (format specific)

-ignore_extra_input

Added in version 3.9.

Set this flag to avoid extra non-numeric content at end of input lines to be appended to the output lines in -valonly mode (requires *-field_sep* to be also defined), or as a dedicated field in default or *-xml* modes.

-E

Added in version 3.9.

Enable Echo mode, where input coordinates are prepended to the output lines in *-valonly* mode.

-field_sep <sep>

Added in version 3.9.

Defines the field separator, used in *-valonly* mode, to separate different values. It defaults to the new-line character, which means that when querying a raster with several bands, the output will contain one value per line, which may make it hard to recognize which value belongs to which set of input x,y points when several ones are provided. Defining the field separator is also needed

<srcfile>

The source GDAL raster datasource name.

<x>

X location of target pixel. By default the coordinate system is pixel/line unless -l_srs, -wgs84 or -geoloc supplied.

<y>

Y location of target pixel. By default the coordinate system is pixel/line unless -l_srs, -wgs84 or -geoloc supplied.

This utility is intended to provide a variety of information about a pixel. Currently it reports:

- The location of the pixel in pixel/line space.

- The result of a LocationInfo metadata query against the datasource. This is implemented for VRT files which will report the file(s) used to satisfy requests for that pixel, and by the *MBTiles* driver.
- The raster pixel value of that pixel for all or a subset of the bands.
- The unscaled pixel value if a Scale and/or Offset apply to the band.

The pixel selected is requested by x/y coordinate on the command line, or read from stdin. More than one coordinate pair can be supplied when reading coordinates from stdin. By default integer pixel/line coordinates are expected. However with use of the `-geoloc`, `-wgs84`, or `-l_srs` switches it is possible to specify the location in other coordinate systems.

The default report is in a human readable text format. It is possible to instead request xml output with the -xml switch.

For scripting purposes, the -valonly and -lifonly switches are provided to restrict output to the actual pixel values, or the LocationInfo files identified for the pixel.

It is anticipated that additional reporting capabilities will be added to gdallocationinfo in the future.

Return status code

The program returns status code 0 in case of success, and non-zero in case of error (non-blocking errors emitted as warnings are considered as a successful execution).

Examples

Example 1: Reporting on pixel (256,256) on the file utm.tif

```
$ gdallocationinfo utm.tif 256 256
Report:
Location: (256P,256L)
Band 1:
    Value: 115
```

Example 2: Querying a VRT file providing the location in WGS84, and getting the result in XML

```
$ gdallocationinfo -xml -wgs84 utm.vrt -117.5 33.75
<Report pixel="217" line="282">
    <BandReport band="1">
        <LocationInfo>
        <File>utm.tif</File>
        </LocationInfo>
        <Value>16</Value>
    </BandReport>
</Report>
```

Example 3: Reading locations from stdin

```
$ cat coordinates.txt
443020 3748359
441197 3749005
443852 3747743

$ cat coordinates.txt | gdallocationinfo -geoloc utmsmall.tif
Report:
```

(continues on next page)

(continued from previous page)

```
  Location: (38P,49L)
  Band 1:
    Value: 214
Report:
  Location: (7P,38L)
  Band 1:
    Value: 107
Report:
  Location: (52P,59L)
  Band 1:
    Value: 148

$ cat coordinates.txt | gdallocationinfo -geoloc -valonly -E -field_sep , utmsmall.tif
443020,3748359,214
441197,3749005,107
443852,3747743,148
```

5.2.2.29 gdalmanage

Synopsis

```
Usage: gdalmanage [--help] [--help-general]
                  <mode> [-r] [-fr] [-u] [-f <format>]
                  <datasetname> [<newdatasetname>]
```

Description

The **gdalmanage** program can perform various operations on dataset files, depending on the chosen *mode*. This includes identifying dataset types and deleting, renaming or copying the files.

<mode>

Mode of operation

identify <*datasetname*>:
List data format of file(s).

copy <*datasetname*> <*newdatasetname*>:
Create a copy of the dataset file with a new name.

rename <*datasetname*> <*newdatasetname*>:
Change the name of the dataset file.

delete <*datasetname*>:
Delete dataset file(s).

-r

Recursively scan files/folders for dataset files.

-fr

Recursively scan folders for dataset files, forcing recursion in folders recognized as valid formats.

-u

Report failures if file type is unidentified.

-f <format>

Specify format of dataset file if unknown by the application. Uses short data format name (e.g. *GTiff*).

<datasetname>

Raster file to operate on. With **identify** may be repeated for multiple files.

<newdatasetname>

For copy and rename modes, you provide a *source* filename and a *target* filename, just like copy and move commands in an operating system.

Return status code

The program returns status code 0 in case of success, and non-zero in case of error (non-blocking errors emitted as warnings are considered as a successful execution).

Examples

Using identify mode

Report the data format of the dataset file by using the *identify* mode and specifying a data file name:

```
$ gdalmanage identify NE1_50M_SR_W.tif

NE1_50M_SR_W.tif: GTiff
```

Recursive mode will scan subfolders and report the data format:

```
$ gdalmanage identify -r 50m_raster/

NE1_50M_SR_W/ne1_50m.jpg: JPEG
NE1_50M_SR_W/ne1_50m.png: PNG
NE1_50M_SR_W/ne1_50m_20pct.tif: GTiff
NE1_50M_SR_W/ne1_50m_band1.tif: GTiff
NE1_50M_SR_W/ne1_50m_print.png: PNG
NE1_50M_SR_W/NE1_50M_SR_W.aux: HFA
NE1_50M_SR_W/NE1_50M_SR_W.tif: GTiff
NE1_50M_SR_W/ne1_50m_sub.tif: GTiff
NE1_50M_SR_W/ne1_50m_sub2.tif: GTiff
```

Using copy mode

Copy the dataset:

```
$ gdalmanage copy NE1_50M_SR_W.tif ne1_copy.tif
```

Using rename mode

Rename dataset:

```
$ gdalmanage rename NE1_50M_SR_W.tif ne1_rename.tif
```

Using delete mode

Delete the dataset:

```
gdalmanage delete NE1_50M_SR_W.tif
```

5.2.2.30 gdalmove

Synopsis

```
gdalmove [--help] [--help-general]
            [-s_srs <srs_defn>] -t_srs <srs_defn>
            [-et <max_pixel_err>] <target_file>
```

Description

The **gdalmove** script transforms the bounds of a raster file from one coordinate system to another, and then updates the coordinate system and geotransform of the file. This is done without altering pixel values at all. It is loosely similar to using gdalwarp to transform an image but avoiding the resampling step in order to avoid image damage. It is generally only suitable for transformations that are effectively linear in the area of the file.

If no error threshold value (*-et*) is provided then the file is not actually updated, but the errors that would be incurred are reported. If *-et* is provided then the file is only modify if the apparent error being introduced is less than the indicate threshold (in pixels).

Currently the transformed geotransform is computed based on the transformation of the top left, top right, and bottom left corners. A reduced overall error could be produced using a least squares fit of at least all four corner points.

> **Note**
>
> gdalmove is a Python utility, and is only available if GDAL Python bindings are available.

--help

Show this help message and exit

--help-general

Gives a brief usage message for the generic GDAL commandline options and exit.

-s_srs <srs_defn>

Override the coordinate system of the file with the indicated coordinate system definition. Optional. If not provided the source coordinate system is read from the source file.

-t_srs <srs_defn>

Defines the target coordinate system. This coordinate system will be written to the file after an update.

-et <max_pixel_err>

The error threshold (in pixels) beyond which the file will not be updated. If not provided no update will be applied to the file, but errors will be reported.

<target_file>

The file to be operated on. To update this must be a file format that supports in place updates of the geotransform and SRS.

Return status code

The program returns status code 0 in case of success, and non-zero in case of error (non-blocking errors emitted as warnings are considered as a successful execution).

5.2.2.31 gdalsrsinfo

Synopsis

```
Usage: gdalsrsinfo [--help] [--help-general]
                   [--single-line] [-V] [-e][-o <out_type>] <srs_def>
```

Description

The **gdalsrsinfo** utility reports information about a given SRS from one of the following:

- The filename of a dataset supported by GDAL/OGR which contains SRS information
- Any of the usual GDAL/OGR forms (complete WKT, PROJ.4, EPSG:n or a file containing the SRS)

--help

Show this help message and exit

--help-general

Gives a brief usage message for the generic GDAL commandline options and exit.

--single-line

Print WKT on single line

-V

Validate SRS

-e

Search for EPSG number(s) corresponding to SRS

-o <out_type>

Output types:

- `default`: proj4 and wkt (default option)
- `all`: all options available
- `wkt_all`: all wkt options available
- `PROJJSON`: PROJJSON string (GDAL >= 3.1 and PROJ >= 6.2)
- `proj4`: PROJ.4 string
- `wkt1`: OGC WKT format (full)
- `wkt_simple`: OGC WKT 1 (simplified)
- `wkt_noct`: OGC WKT 1 (without OGC CT params)
- `wkt_esri`: ESRI WKT format
- `wkt`: Latest WKT version supported, currently wkt2_2019
- `wkt2`: Latest WKT2 version supported, currently wkt2_2019
- `wkt2_2015`: OGC WKT2:2015
- `wkt2_2019`: OGC WKT2:2019 (for GDAL < 3.6, use `wkt2_2018`)

- `mapinfo`: Mapinfo style CoordSys format
- `xml`: XML format (GML based)

<srs_def>

may be the filename of a dataset supported by GDAL/OGR from which to extract SRS information OR any of the usual GDAL/OGR forms (complete WKT, PROJ.4, EPSG:n or a file containing the SRS)

Return status code

The program returns status code 0 in case of success, and non-zero in case of error (non-blocking errors emitted as warnings are considered as a successful execution).

Example

Example 1

Default output

```
$ gdalsrsinfo EPSG:4326

PROJ.4 : +proj=longlat +datum=WGS84 +no_defs

OGC WKT2:2019 :
GEOGCRS["WGS 84",

```

Description

This program creates an OGR-supported dataset with a record for each input raster file, an attribute containing the filename, and a polygon geometry outlining the raster. This output is suitable for use with MapServer as a raster tileindex, or as input for the *GTI* driver.

Tip

Equivalent in new "gdal" command line interface:

See *gdal raster index*.

--help

Show this help message and exit

--help-general

Gives a brief usage message for the generic GDAL commandline options and exit.

-q, --quiet

Suppress progress messages and other non-error output.

-overwrite

Added in version 3.9.

Overwrite the tile index if it already exists.

-recursive

Added in version 3.9.

Whether directories specified in <file_or_dir> should be explored recursively.

-filename_filter <val>

Added in version 3.9.

Pattern that the filenames contained in directories pointed by <file_or_dir> should follow. '*' is a wildcard character that matches any number of any characters including none. '?' is a wildcard character that matches a single character. Comparisons are done in a case insensitive way. Several filters may be specified.

For example :`-filename_filter "*.tif" -filename_filter "*.tiff"`

-min_pixel_size <val>

Added in version 3.9.

Minimum pixel size in term of geospatial extent per pixel (resolution) that a raster should have to be selected. The pixel size is evaluated after reprojection of its extent to the target SRS defined by *-t_srs*.

-max_pixel_size <val>

Added in version 3.9.

Maximum pixel size in term of geospatial extent per pixel (resolution) that a raster should have to be selected. The pixel size is evaluated after reprojection of its extent to the target SRS defined by *-t_srs*.

-of <output_format>

The OGR format of the output tile index file. If not specified, the format is guessed from the extension.

-tileindex <field_name>

The output field name to hold the file path/location to the indexed rasters. The default tile index field name is `location`.

-write_absolute_path

The absolute path to the raster files is stored in the tile index file. By default the raster filenames will be put in the file exactly as they are specified on the command line.

-skip_different_projection

Only files with same projection as files already inserted in the tileindex will be inserted (unless *-t_srs* is specified). Default does not check projection and accepts all inputs.

-t_srs <target_srs>

Geometries of input files will be transformed to the desired target coordinate reference system. Default creates simple rectangular polygons in the same coordinate reference system as the input rasters.

-src_srs_name <field_name>

The name of the field to store the SRS of each tile. This field name can be used as the value of the TILESRS keyword in MapServer

-src_srs_format {AUTO|WKT|EPSG|PROJ}

The format in which the SRS of each tile must be written. Types can be `AUTO`, `WKT`, `EPSG`, `PROJ`. This option should be used together with *-src_srs_format*.

-lyr_name <name>

Layer name to create/append to in the output tile index file.

-lco <NAME>=<VALUE>

Added in version 3.9.

Layer creation option (format specific)

<index_file>

The name of the output file to create/append to. The default dataset will be created if it doesn't already exist, otherwise it will append to the existing dataset.

<file_or_dir>

The input GDAL raster files, can be multiple files separated by spaces. Wildcards may also be used. Stores the file locations in the same style as specified here, unless *-write_absolute_path* option is also used.

Starting with GDAL 3.9, this can also be a directory name. *-recursive* can also be used to recurse down to sub-directories.

It is also possible to use the generic option `--optfile filelist.txt` to specify a list of source files.

Options specific to use by the GDAL GTI driver

gdaltindex can be used to generate a tile index suitable for use by the *GTI* driver. There are two possibilities:

- either use directly a vector tile index generated by gdaltindex as the input of the GTI driver
- or generate a small XML .gti wrapper file, for easier use with non-file-based formats such as databases, or for vector formats that do not support setting layer metadata items.

Formats that support layer metadata are for example GeoPackage (`-of GPKG`), FlatGeoBuf (`-of FlatGeoBuf`) or PostGIS (`-of PG`)

Setting *-tr* and *-ot* is recommended to avoid the GTI driver to have to deduce them by opening the first tile in the index. If the tiles have nodata or mask band, *-nodata* and *-mask* should also be set.

In a GTI context, the extent of all tiles referenced in the tile index must be expressed in a single SRS. Consequently, if input tiles may have different SRS, either *-t_srs* or *-skip_different_projection* should be specified.

-gti_filename <name>

Added in version 3.9.

Filename of the XML Virtual Tile Index file to generate, that can be used as an input for the GDAL GTI / Virtual Raster Tile Index driver. This can be useful when writing the tile index in a vector format that does not support writing layer metadata items.

-tr <xres> <yres>

Added in version 3.9.

Target resolution in SRS unit per pixel.

Written in the XML Virtual Tile Index if *-gti_filename* is specified, or as RESX and RESY layer metadata items for formats that support layer metadata.

-te <xmin> <ymin> <xmax> <ymax>

Added in version 3.9.

Target extent in SRS unit.

Written in the XML Virtual Tile Index if *-gti_filename* is specified, or as MINX, MINY, MAXX and MAXY layer metadata items for formats that support layer metadata.

-ot <datatype>

Added in version 3.9.

Data type of the tiles of the tile index: Byte, Int8, UInt16, Int16, UInt32, Int32, UInt64, Int64, Float32, Float64, CInt16, CInt32, CFloat32 or CFloat64

Written in the XML Virtual Tile Index if *-gti_filename* is specified, or as DATA_TYPE layer metadata item for formats that support layer metadata.

-bandcount <val>

Added in version 3.9.

Number of bands of the tiles of the tile index.

Written in the XML Virtual Tile Index if *-gti_filename* is specified, or as BAND_COUNT layer metadata item for formats that support layer metadata.

A mix of tiles with N and N+1 bands is allowed, provided that the color interpretation of the (N+1)th band is alpha. The N+1 value must be written as the band count in that situation.

If *-nodata* or *-colorinterp* are specified and have multiple values, the band count is also inferred from that number.

-nodata <val>[,<val>...]

Added in version 3.9.

Nodata value of the tiles of the tile index.

Written in the XML Virtual Tile Index if *-gti_filename* is specified, or as NODATA layer metadata item for formats that support layer metadata.

-colorinterp <val>[,<val>...]

Added in version 3.9.

Color interpretation of of the tiles of the tile index: `red`, `green`, `blue`, `alpha`, `gray`, `undefined`.

Written in the XML Virtual Tile Index if *-gti_filename* is specified, or as `COLOR_INTERPRETATION` layer metadata item for formats that support layer metadata.

-mask

Added in version 3.9.

Whether tiles in the tile index have a mask band.

Written in the XML Virtual Tile Index if *-gti_filename* is specified, or as `MASK_BAND` layer metadata item for formats that support layer metadata.

-mo <KEY>=<VALUE>

Added in version 3.9.

Write an arbitrary layer metadata item, for formats that support layer metadata. This option may be repeated.

> **Note**
>
> This option cannot be used together *-gti_filename*

-fetch_md <gdal_md_name> <fld_name> <fld_type>

Added in version 3.9.

Fetch a metadata item from the raster tile and write it as a field in the tile index.

<gdal_md_name> should be the name of the raster metadata item. `{PIXEL_SIZE}` may be used as a special name to indicate the pixel size.

<fld_name> should be the name of the field to create in the tile index.

<fld_type> should be the name of the type to create. One of `String`, `Integer`, `Integer64`, `Real`, `Date`, `DateTime`

This option may be repeated.

For example: `-fetch_md TIFFTAG_DATETIME creation_date DateTime`

Examples

Example 1

Produce a shapefile (`doq_index.shp`) with a record for every image that the utility found in the `doq` folder. Each record holds information that points to the location of the image and also a bounding rectangle shape showing the bounds of the image:

```
gdaltindex doq_index.shp doq/*.tif
```

Example 2

Perform the same command as before, but now we create a GeoPackage instead of a Shapefile.

```
gdaltindex -of GPKG doq_index.gpkg doq/*.tif
```

Example 3

The *-t_srs* option can also be used to transform all input rasters into the same output projection:

```
gdaltindex -t_srs EPSG:4326 -src_srs_name src_srs tile_index_mixed_srs.shp *.tif
```

Example 4

Make a tile index from files listed in a text file, with metadata suitable for use by the GDAL GTI / Virtual Raster Tile Index driver.

```
gdaltindex tile_index.gti.gpkg -ot Byte -tr 60 60 -colorinterp Red,Green,Blue --optfile␣
↪my_list.txt
```

Return status code

The program returns status code 0 in case of success, and non-zero in case of error (non-blocking errors emitted as warnings are considered as a successful execution).

C API

This utility is also callable from C with *GDALTileIndex()*.

See also

Common options for raster programs for other command-line options, and in particular the *--optfile* switch that can be used to specify a list of input datasets.

5.2.2.33 gdaltransform

Synopsis

```
Usage: gdaltransform [--help] [--help-general]
       [-i] [-s_srs <srs_def>] [-t_srs <srs_def>] [-to >NAME>=<VALUE>]...
       [-s_coord_epoch <epoch>] [-t_coord_epoch <epoch>]
       [-ct <proj_string>] [-order <n>] [-tps] [-rpc] [-geoloc]
       [-gcp <pixel> <line> <easting> <northing> [elevation]]...
       [-output_xy] [-E] [-field_sep <sep>] [-ignore_extra_input]
       [<srcfile> [<dstfile>]]
```

Description

The gdaltransform utility reprojects a list of coordinates into any supported projection,including GCP-based transformations.

--help

Show this help message and exit

--help-general

Gives a brief usage message for the generic GDAL commandline options and exit.

-s_srs <srs_def>

Set source spatial reference. The coordinate systems that can be passed are anything supported by the OGRSpatialReference.SetFromUserInput() call, which includes EPSG PCS and GCSes (i.e. EPSG:4296), PROJ.4 declarations (as above), or the name of a .prj file containing well known text.

-s_coord_epoch <epoch>

Added in version 3.8.

Assign a coordinate epoch, linked with the source SRS. Useful when the source SRS is a dynamic CRS. Only taken into account if *-s_srs* is used.

Before PROJ 9.4, *-s_coord_epoch* and *-t_coord_epoch* were mutually exclusive, due to lack of support for transformations between two dynamic CRS.

-t_srs <srs_def>

set target spatial reference. The coordinate systems that can be passed are anything supported by the OGRSpatialReference.SetFromUserInput() call, which includes EPSG PCS and GCSes (i.e. EPSG:4296), PROJ.4 declarations (as above), or the name of a .prj file containing well known text.

-t_coord_epoch <epoch>

Added in version 3.8.

Assign a coordinate epoch, linked with the output SRS. Useful when the output SRS is a dynamic CRS. Only taken into account if *-t_srs* is used.

Before PROJ 9.4, *-s_coord_epoch* and *-t_coord_epoch* were mutually exclusive, due to lack of support for transformations between two dynamic CRS.

-ct <string>

A PROJ string (single step operation or multiple step string starting with +proj=pipeline), a WKT2 string describing a CoordinateOperation, or a urn:ogc:def:coordinateOperation:EPSG::XXXX URN overriding the default transformation from the source to the target CRS. It must take into account the axis order of the source and target CRS.

Added in version 3.0.

-to <NAME>=<VALUE>

set a transformer option suitable to pass to *GDALCreateGenImgProjTransformer2()*.

-order <n>

order of polynomial used for warping (1 to 3). The default is to select a polynomial order based on the number of GCPs.

-tps

Force use of thin plate spline transformer based on available GCPs.

-rpc

Force use of RPCs.

-geoloc

Force use of Geolocation Arrays.

-i

Inverse transformation: from destination to source.

-gcp <pixel> <line> <easting> <northing> [<elevation>]

Provide a GCP to be used for transformation (generally three or more are required). Pixel and line need not be integers.

-output_xy

Restrict output to "x y" instead of "x y z"

-ignore_extra_input

Added in version 3.9.

Set this flag to avoid extra non-numeric content at end of input lines to be appended to the output lines.

-E

Added in version 3.9.

Enable Echo mode, where input coordinates are prepended to the output lines.

-field_sep <sep>

Added in version 3.9.

Defines the field separator, to separate different values. It defaults to the space character.

<srcfile>

Raster dataset with source projection definition or GCPs. If not given, source projection/GCPs are read from the command-line *-s_srs* or *-gcp* parameters.

Note that only the SRS and/or GCPs of this input file is taken into account, and not its pixel content.

<dstfile>

Raster dataset with destination projection definition.

Coordinates are read as pairs, triples (for 3D,) or (since GDAL 3.0.0,) quadruplets (for X,Y,Z,time) of numbers per line from standard input, transformed, and written out to standard output in the same way. All transformations offered by gdalwarp are handled, including gcp-based ones.

Starting with GDAL 3.9, additional non-numeric content (typically point name) at the end of an input line will also be appended to the output line, unless the *-ignore_extra_input* is added.

Note that input and output must always be in decimal form. There is currently no support for DMS input or output.

If an input image file is provided, input is in pixel/line coordinates on that image. If an output file is provided, output is in pixel/line coordinates on that image.

Return status code

The program returns status code 0 in case of success, and non-zero in case of error (non-blocking errors emitted as warnings are considered as a successful execution).

Examples

Reprojection Example

Simple reprojection from one projected coordinate system to another:

```
gdaltransform -s_srs EPSG:28992 -t_srs EPSG:31370
177502 311865
```

Produces the following output in meters in the "Belge 1972 / Belgian Lambert 72" projection:

```
244296.724777415 165937.350217148 0
```

Image RPC Example

The following command requests an RPC based transformation using the RPC model associated with the named file. Because the -i (inverse) flag is used, the transformation is from output georeferenced (WGS84) coordinates back to image coordinates.

```
gdaltransform -i -rpc 06OCT20025052-P2AS-005553965230_01_P001.TIF
125.67206 39.85307 50
```

Produces this output measured in pixels and lines on the image:

```
3499.49282422381 2910.83892848414 50
```

X,Y,Z,time transform

15-term time-dependent Helmert coordinate transformation from ITRF2000 to ITRF93 for a coordinate at epoch 2000.0

```
gdaltransform -ct "+proj=pipeline +step +proj=unitconvert +xy_in=deg \
+xy_out=rad +step +proj=cart +step +proj=helmert +convention=position_vector \
+x=0.0127 +dx=-0.0029 +rx=-0.00039 +drx=-0.00011 +y=0.0065 +dy=-0.0002 \
+ry=0.00080 +dry=-0.00019 +z=-0.0209 +dz=-0.0006 +rz=-0.00114 +drz=0.00007 \
+s=0.00195 +ds=0.00001 +t_epoch=1988.0 +step +proj=cart +inv +step \
+proj=unitconvert +xy_in=rad +xy_out=deg"
2 49 0 2000
```

Produces this output measured in longitude degrees, latitude degrees and ellipsoid height in meters:

```
2.0000005420366 49.0000003766711 -0.0222802283242345
```

Ground control points

Task: find one address and assign another. We pick Salt Lake City, where road names *are* their grid values. We first establish some ground control points at road intersections. We'll use *--optfile* for easy reuse of our GCPs.

```
echo -output_xy \
-gcp 0   0    -111.89114717 40.76932606 \
-gcp 0   -500 -111.89114803 40.75846686 \
-gcp 500 0    -111.87685039 40.76940631 > optfile.txt
```

Where is the address "370 S. 300 E."?

```
echo 300 -370 Address 370 S. 300 E. | gdaltransform --optfile optfile.txt
-111.8825697384 40.761338402 Address 370 S. 300 E.
```

(The 370 is protected from being consumed as an elevation by placing a word before it.)

Nearby, a newly constructed building needs an address assigned. We use *-i*:

```
echo -111.88705 40.76502 Building ABC123 | gdaltransform -i --optfile optfile.txt
143.301947786644 -199.32683635161 Building ABC123
```

(i.e., 143 E. 200 S. Or 144 if across the street.)

5.2.2.34 gdalwarp

Synopsis

```
Usage: gdalwarp [--help] [--long-usage] [--help-general]
                [--quiet] [-overwrite] [-of <output_format>]
```

(continues on next page)

(continued from previous page)

```
                [-co <NAME>=<VALUE>]... [-s_srs <srs_def>] [-t_srs <srs_def>]
                [[-srcalpha]|[-nosrcalpha]]
                [-dstalpha] [-tr <xres> <yres>|square] [-ts <width> <height>]
                [-te <xmin> <ymin> <xmax> <ymax>] [-te_srs <srs_def>]
                [-r␣
↪near|bilinear|cubic|cubicspline|lanczos|average|rms|mode|min|max|med|q1|q3|sum]
                [-ot Byte|Int8|[U]Int{16|32|64}|CInt{16|32}|[C]Float{32|64}]
                <src_dataset_name>... <dst_dataset_name>

Advanced options:
                [-wo <NAME>=<VALUE>]... [-multi] [-s_coord_epoch <epoch>]
                [-t_coord_epoch <epoch>] [-ct <string>]
                [[-tps]|[-rpc]|[-geoloc]]
                [-order <1|2|3>] [-refine_gcps <tolerance> [<minimum_gcps>]]

```

Description

The **gdalwarp** utility is an image mosaicing, reprojection and warping utility. The program can reproject to any supported projection, and can also apply GCPs stored with the image if the image is "raw" with control information.

> **Tip**
>
> Equivalent in new "gdal" command line interface:
>
> - *gdal raster reproject* for reprojection
> - *gdal raster update* to update the content of a raster with another one

--help

Show this help message and exit

--help-general

Gives a brief usage message for the generic GDAL commandline options and exit.

-q, --quiet

Suppress progress messages and other non-error output.

-b <n>

-srcband <n>

Added in version 3.7.

Specify an input band number to warp (between 1 and the number of bands of the source dataset).

This option is used to warp a subset of the input bands. All input bands are used when it is not specified.

This option may be repeated multiple times to select several input bands. The order in which bands are specified will be the order in which they appear in the output dataset (unless *-dstband* is specified).

The alpha band should not be specified in the list, as it will be automatically retrieved (unless *-nosrcalpha* is specified).

The following invocation will warp an input datasets with bands ordered as Blue, Green, Red, NearInfraRed in an output dataset with bands ordered as Red, Green, Blue.

```
gdalwarp in_bgrn.tif out_rgb.tif -b 3 -b 2 -b 1 -overwrite
```

-dstband <n>

Added in version 3.7.

Specify the output band number in which to warp. In practice, this option is only useful when updating an existing dataset, e.g to warp one band at at time.

```
gdal_create -if in_red.tif -bands 3 out_rgb.tif
gdalwarp in_red.tif out_rgb.tif -srcband 1 -dstband 1
gdalwarp in_green.tif out_rgb.tif -srcband 1 -dstband 2
gdalwarp in_blue.tif out_rgb.tif -srcband 1 -dstband 3
```

If *-srcband* is specified, there must be as many occurrences of *-dstband* as there are of *-srcband*.

The output alpha band should not be specified, as it will be automatically created if the input dataset has an alpha band, or if *-dstalpha* is specified.

If *-dstband* is not specified, then `-dstband 1 -dstband 2 ... -dstband N` is assumed where N is the number of input bands (specified explicitly either with *-srcband* or implicitly)

-s_srs <srs def>

Set source spatial reference. If not specified the SRS found in the input dataset will be used.

The coordinate reference systems that can be passed are anything supported by the OGRSpatialReference.SetFromUserInput() call, which includes EPSG Projected, Geographic or Compound CRS (i.e. EPSG:4296), a well known text (WKT) CRS definition, PROJ.4 declarations, or the name of a .prj file containing a WKT CRS definition.

If the SRS has an explicit vertical datum that points to a geoid grid, and the input dataset is a single band dataset, a vertical correction will be applied to the values of the dataset.

-s_coord_epoch <epoch>

Added in version 3.4.

Assign a coordinate epoch, linked with the source SRS. Useful when the source SRS is a dynamic CRS. Only taken into account if *-s_srs* is used.

Before PROJ 9.4, *-s_coord_epoch* and *-t_coord_epoch* were mutually exclusive, due to lack of support for transformations between two dynamic CRS.

-t_srs <srs_def>

Set target spatial reference.

A source SRS must be available for reprojection to occur. The source SRS will be by default the one found in the input dataset when it is available, or as overridden by the user with *-s_srs*

The coordinate reference systems that can be passed are anything supported by the OGRSpatialReference.SetFromUserInput() call, which includes EPSG Projected, Geographic or Compound CRS (i.e.

EPSG:4296), a well known text (WKT) CRS definition, PROJ.4 declarations, or the name of a .prj file containing a WKT CRS definition.

If the SRS has an explicit vertical datum that points to a geoid grid, and the input dataset is a single band dataset, a vertical correction will be applied to the values of the dataset.

-t_coord_epoch <epoch>

Added in version 3.4.

Assign a coordinate epoch, linked with the target SRS. Useful when the target SRS is a dynamic CRS. Only taken into account if *-t_srs* is used.

Before PROJ 9.4, *-s_coord_epoch* and *-t_coord_epoch* were mutually exclusive, due to lack of support for transformations between two dynamic CRS.

-ct <string>

A PROJ string (single step operation or multiple step string starting with +proj=pipeline), a WKT2 string describing a CoordinateOperation, or a urn:ogc:def:coordinateOperation:EPSG::XXXX URN overriding the default transformation from the source to the target CRS.

It must take into account the axis order of the source and target CRS, that is typically include a `step proj=axisswap order=2,1` at the beginning of the pipeline if the source CRS has northing/easting axis order, and/or at the end of the pipeline if the target CRS has northing/easting axis order.

When creating a new output file, using *-t_srs* is still necessary to have the target CRS written in the metadata of the output file, but the parameters of the CoordinateOperation will override those of the standard transformation.

Added in version 3.0.

-to <NAME>=<VALUE>

Set a transformer option suitable to pass to *GDALCreateGenImgProjTransformer2()*. See *GDALCreateRPCTransformerV2()* for RPC specific options.

-vshift

Force the use of vertical shift. This option is generally not necessary, except when using an explicit coordinate transformation (*-ct*), and not specifying an explicit source and target SRS.

Added in version 3.4.

-novshift

Disable the use of vertical shift when one of the source or target SRS has an explicit vertical datum, and the input dataset is a single band dataset.

> **Note**
>
> this option was named `-novshiftgrid` until GDAL 3.3.

Added in version 3.4.

-order <n>

order of polynomial used for warping (1 to 3). The default is to select a polynomial order based on the number of GCPs.

-tps

Force use of Thin Plate Spline transformer based on available GCPs.

> **Warning**
>
> Using a Thin Plate Spline transformer with more than a few thousand GCPs requires significant RAM usage (at least `numGCPs` * `numGCPs` * 8 bytes) and processing time.

-rpc

Force use of RPCs.

-geoloc

Force use of Geolocation Arrays.

-et `<err_threshold>`

Error threshold for transformation approximation, expressed as a number of source pixels. Defaults to 0.125 pixels unless the `RPC_DEM` transformer option is specified, in which case an exact transformer, i.e. `err_threshold=0`, will be used.

-refine_gcps `<tolerance> [<minimum_gcps>]`

Refines the GCPs by automatically eliminating outliers. Outliers will be eliminated until minimum_gcps are left or when no outliers can be detected. The tolerance is passed to adjust when a GCP will be eliminated. Note that GCP refinement only works with polynomial interpolation. The tolerance is in pixel units if no projection is available, otherwise it is in SRS units. If minimum_gcps is not provided, the minimum GCPs according to the polynomial model is used.

-te `<xmin> <ymin> <xmax> <ymax>`

Set georeferenced extents of output file to be created (in target SRS by default, or in the SRS specified with *-te_srs*)

-te_srs `<srs_def>`

Specifies the SRS in which to interpret the coordinates given with -te. The <srs_def> may be any of the usual GDAL/OGR forms, complete WKT, PROJ.4, EPSG:n or a file containing the WKT. This must not be confused with -t_srs which is the target SRS of the output dataset. *-te_srs* is a convenience e.g. when knowing the output coordinates in a geodetic long/lat SRS, but still wanting a result in a projected coordinate system.

-tr `<xres> <yres> | -tr square`

Set output file resolution (in target georeferenced units).

If not specified (or not deduced from -te and -ts), gdalwarp will, in the general case, generate an output raster with xres=yres.

Starting with GDAL 3.7, if neither *-tr* nor *-ts* are specified, that no reprojection is involved (including taking into account geolocation arrays or RPC), the resolution of the source file(s) will be preserved (in previous version, an output raster with xres=yres was always generated). It is possible to ask square pixels to still be generated, by specifying `square` as the value for *-tr*.

-tap

(target aligned pixels) align the coordinates of the extent of the output file to the values of the *-tr*, such that the aligned extent includes the minimum extent (edges lines/columns that are detected as blank, before actual warping, will be removed starting with GDAL 3.8). Alignment means that xmin / resx, ymin / resy, xmax / resx and ymax / resy are integer values. It does not necessarily mean that the output grid aligns with the input grid.

-ts `<width> <height>`

Set output file size in pixels and lines. If width or height is set to 0, the other dimension will be guessed from the computed resolution. Note that *-ts* cannot be used with *-tr*

-ovr <level>|AUTO|AUTO-<n>|NONE

To specify which overview level of source files must be used. The default choice, AUTO, will select the overview level whose resolution is the closest to the target resolution. Specify an integer value (0-based, i.e. 0=1st overview level) to select a particular level. Specify AUTO-n where n is an integer greater or equal to 1, to select an overview level below the AUTO one. Or specify NONE to force the base resolution to be used (can be useful if overviews have been generated with a low quality resampling method, and the warping is done using a higher quality resampling method).

-wo <NAME>=<VALUE>

Set a warp option. The *GDALWarpOptions::papszWarpOptions* docs show all options. Multiple *-wo* options may be listed.

-ot <type>

Force the output image bands to have a specific data type supported by the driver, which may be one of the following: `Byte`, `Int8`, `UInt16`, `Int16`, `UInt32`, `Int32`, `UInt64`, `Int64`, `Float32`, `Float64`, `CInt16`, `CInt32`, `CFloat32` or `CFloat64`.

-wt <type>

Working pixel data type. The data type of pixels in the source image and destination image buffers.

-r <resampling_method>

Resampling method to use. Available methods are:

`near`: nearest neighbour resampling (default for non-COG drivers, fastest algorithm, worst interpolation quality).

`bilinear`: bilinear resampling.

`cubic`: cubic resampling (default for COG driver).

`cubicspline`: cubic spline resampling.

`lanczos`: Lanczos windowed sinc resampling.

`average`: average resampling, computes the weighted average of all non-NODATA contributing pixels.

`rms` root mean square / quadratic mean of all non-NODATA contributing pixels (GDAL >= 3.3)

`mode`: mode resampling, selects the value which appears most often of all the sampled points. In the case of ties, the first value identified as the mode will be selected.

`max`: maximum resampling, selects the maximum value from all non-NODATA contributing pixels.

`min`: minimum resampling, selects the minimum value from all non-NODATA contributing pixels.

`med`: median resampling, selects the median value of all non-NODATA contributing pixels.

`q1`: first quartile resampling, selects the first quartile value of all non-NODATA contributing pixels.

`q3`: third quartile resampling, selects the third quartile value of all non-NODATA contributing pixels.

`sum`: compute the weighted sum of all non-NODATA contributing pixels (since GDAL 3.1)

> **Note**
>
> When downsampling is performed (use of *-tr* or *-ts*), existing overviews (either internal/implicit or external ones) on the source image will be used by default by selecting the closest overview to the desired output resolution. The resampling method used to create those overviews is generally not the one you specify through the *-r* option. Some formats, like JPEG2000, can contain significant outliers due to how wavelet compression works. It might thus be useful in those situations to use the *-ovr* `NONE` option to prevent existing overviews to be used.

-srcnodata "<value>[<value>]..."

Set nodata masking values for input bands (different values can be supplied for each band). If more than one value is supplied all values should be quoted to keep them together as a single operating system argument. Masked values will not be used in interpolation (details given in *Nodata / source validity mask handling*)

Use a value of `None` to ignore intrinsic nodata settings on the source dataset.

When this option is set to a non-`None` value, it causes the `UNIFIED_SRC_NODATA` warping option (see *GDALWarpOptions::papszWarpOptions*) to be set to `YES`, if it is not explicitly set.

If `-srcnodata` is not explicitly set, but the source dataset has nodata values, they will be taken into account, with `UNIFIED_SRC_NODATA` at `PARTIAL` by default.

-dstnodata "<value>[<value>]..."

Set nodata values for output bands (different values can be supplied for each band). If more than one value is supplied all values should be quoted to keep them together as a single operating system argument. New files will be initialized to this value and if possible the nodata value will be recorded in the output file. Use a value of `None` to ensure that nodata is not defined. If this argument is not used then nodata values will be copied from the source dataset.

-srcalpha

Force the last band of a source image to be considered as a source alpha band.

-nosrcalpha

Prevent the alpha band of a source image to be considered as such (it will be warped as a regular band)

-dstalpha

Create an output alpha band to identify nodata (unset/transparent) pixels.

-wm <memory_in_mb>

Set the amount of memory that the warp API is allowed to use for caching. Defaults to 64 MB. Since GDAL 3.10, the value can be specified either as a fixed amount of memory (e.g., `-wm 200MB`, `-wm 1G`) or as a percentage of usable RAM (`-wm 10%`). In earlier versions, or if a unit is not specified, the value is interpreted as being in megabytes if the value is less than 10000. For values >=10000, it is interpreted as bytes.

The warper will total up the memory required to hold the input and output image arrays and any auxiliary masking arrays and if they are larger than the "warp memory" allowed it will subdivide the chunk into smaller chunks and try again.

If the -wm value is very small there is some extra overhead in doing many small chunks so setting it larger is better but it is a matter of diminishing returns.

-multi

Use multithreaded warping implementation. Two threads will be used to process chunks of image and perform input/output operation simultaneously. Note that computation is not multithreaded itself. To do that, you can use the *-wo* NUM_THREADS=val/ALL_CPUS option, which can be combined with *-multi*

-if <format>

Format/driver name to be attempted to open the input file(s). It is generally not necessary to specify it, but it can be used to skip automatic driver detection, when it fails to select the appropriate driver. This option can be repeated several times to specify several candidate drivers. Note that it does not force those drivers to open the dataset. In particular, some drivers have requirements on file extensions.

Added in version 3.2.

-of <format>

Select the output format. If not specified, the format is guessed from the extension. Use the short format name.

-co <NAME>=<VALUE>

Many formats have one or more optional creation options that can be used to control particulars about the file created. For instance, the GeoTIFF driver supports creation options to control compression, and whether the file should be tiled.

The creation options available vary by format driver, and some simple formats have no creation options at all. A list of options supported for a format can be listed with the *--format* command line option but the documentation for the format is the definitive source of information on driver creation options. See *Raster drivers* format specific documentation for legal creation options for each format.

-cutline <datasource>|<WKT>

Enable use of a blend cutline from the name of a vector dataset. Starting with GDAL 3.9, a WKT geometry string starting with POLYGON or MULTIPOLYGON can also be specified.

-cutline_srs <srs_def>

Added in version 3.9.

Sets or overrides the SRS of the cutline.

-cl <layername>

Select the named layer from the cutline datasource.

-cwhere <expression>

Restrict desired cutline features based on attribute query.

-csql <query>

Select cutline features using an SQL query instead of from a layer with *-cl*.

-cblend <distance>

Set a blend distance to use to blend over cutlines (in pixels).

-crop_to_cutline

Crop the extent of the target dataset to the extent of the cutline.

-overwrite

Overwrite the target dataset if it already exists. Overwriting must be understood here as deleting and recreating the file from scratch. Note that if this option is *not* specified and the output file already exists, it will be updated in place.

-nomd

Do not copy metadata. Without this option, dataset and band metadata (as well as some band information) will be copied from the first source dataset. Items that differ between source datasets will be set to * (see *-cvmd* option).

-cvmd <meta_conflict_value>

Value to set metadata items that conflict between source datasets (default is "*"). Use "" to remove conflicting items.

-setci

Set the color interpretation of the bands of the target dataset from the source dataset.

-oo <NAME>=<VALUE>

Dataset open option (format specific)

-doo <NAME>=<VALUE>

Output dataset open option (format specific)

<src_dataset_name>

The source file name(s).

<dst_dataset_name>

The destination file name.

Overview

gdalwarp transforms images between different coordinate reference systems and spatial resolutions.

First, **gdalwarp** must determine the extent and resolution of the output, if these have not been specified using *-te* and *-tr*. These are determined by transforming a sample of points from the source CRS to the destination CRS. Details of the procedure can be found in the documentation for *GDALSuggestedWarpOutput()*. If multiple inputs are provided to **gdalwarp**, the output extent will be calculated to cover all of them, at a resolution consistent with the highest-resolution input.

Once the dimensions of the output image have been determined, **gdalwarp** divides the output image into chunks that can be processed independently within the amount of memory specified by *-wm*. **gdalwarp** then iterates over scanlines in these chunks, and for each output pixel determines a rectangular region of source pixels that contribute to the value of the output pixel. The dimensions of this rectangular region are typically determined by estimating the relative scales of the source and destination raster, but can be manually specified (see documentation of the `XSCALE` parameter in *GDALWarpOptions::papszWarpOptions*). Because the source region is a simple rectangle, it is not possible for an output pixel to be associated with source pixels from both sides of the antimeridian or pole (when transforming from geographic coordinates).

The rectangular region of source pixels is then provided to a function that performs the resampling algorithm selected with *-r*. Depending on the resampling algorithm and relative scales of the source and destination rasters, source pixels may be weighted either according to the approximate fraction of the source pixel that is covered by the destination pixel (e.g., "mean" and "sum" resampling), or by horizontal and vertical Cartesian distances between the center of the source pixel and the center of the target pixel (e.g., bilinear or cubic spline resampling). In the latter case, the relative weight of an individual source pixel is determined by the product of the weights determined for its row and column; the diagonal Cartesian distance is not calculated.

Multiple input files

When multiple inputs are provided to **gdalwarp**, they are processed independently in the order they are listed. This may introduce edge effects near the boundaries of the input files, because output pixel values will be derived from the final input only. To avoid this, non-overlapping input files may first be combined into a *VRT file* (e.g., using *gdalbuildvrt*). This will allow **gdalwarp** to use pixels from all inputs when calculating output pixel values.

Writing to an existing file

Mosaicing into an existing output file is supported if the output file already exists. The spatial extent of the existing file will not be modified to accommodate new data, so you may have to remove it in that case, or use the *-overwrite* option.

Polygon cutlines may be used as a mask to restrict the area of the destination file that may be updated, including blending. If the OGR layer containing the cutline features has no explicit SRS, the cutline features are assumed to be in the SRS of the destination file. When writing to a not yet existing target dataset, its extent will be the one of the original raster unless *-te* or *-crop_to_cutline* are specified.

Nodata / source validity mask handling

Invalid values in source pixels, either identified through a nodata value metadata set on the source band, a mask band, an alpha band or the use of `-srcnodata` will not be used in interpolation. The details of how it is taken into account depends on the resampling kernel:

- for nearest resampling, for each target pixel, the coordinate of its center is projected back to source coordinates and the source pixel containing that coordinate is identified. If this source pixel is invalid, the target pixel is considered as nodata.
- for bilinear, cubic, cubicspline and lanczos, for each target pixel, the coordinate of its center is projected back to source coordinates and a corresponding source pixel is identified. If this source pixel is invalid, the target pixel is considered as nodata (in this case, valid pixels within the kernel radius would not be considered). Given that those resampling kernels have a non-null kernel radius, this source pixel is just one among other several source pixels, and it might be possible that there are invalid values in those other contributing source pixels. The weights used to take into account those invalid values will be set to zero to ignore them.
- for the other resampling methods, source pixels contributing to the target pixel are ignored if invalid. Only the valid ones are taken into account. If there are none, the target pixel is considered as nodata.

If using `-srcnodata` for multiple images with different invalid values, you need to either (a) pre-process them to have the same to-be-ignored value, or (b) set the nodata flag for each file. Use (b) if you need to preserve the original values for some reason, for example:

```
# for this image we want to ignore black (0)
gdalwarp -srcnodata 0 -dstnodata 0 orig-ignore-black.tif black-nodata.tif

# and now we want to ignore white (0)
gdalwarp -srcnodata 255 -dstnodata 255 orig-ignore-white.tif white-nodata.tif

# and finally ignore a particular blue-grey (RGB 125 125 150)
gdalwarp -srcnodata "125 125 150" -dstnodata "125 125 150" orig-ignore-grey.tif grey-
↪nodata.tif

# now we can mosaic them all and not worry about nodata parameters
gdalwarp black-nodata.tif grey-nodata.tif white-nodata.tif final-mosaic.tif
```

Approximate transformation

By default **gdalwarp** uses a linear approximator for the transformations with a permitted error of 0.125 pixels in the source dataset. For each processing chunk, the approximator precisely transforms three points per output scanline (the start, middle, and end) from a row and column in the output dataset to a row and column in the source dataset. It then compares a linear approximation of the center point coordinates to the precisely transformed value. If the sum of the horizontal and vertical errors is less than the error threshold then the remaining source points are approximated using linear interpolation between the start and middle point, and between the middle and end point. If the error exceeds the threshold, the scanline is split into two sections and the approximator is recursively applied to each section until the error is less than the threshold or all points have been exactly computed.

Note that a processing chunk does not necessarily correspond to a whole destination scanline. If the output dataset is tiled, its shape will typically be one or several tiles. The `OPTIMIZE_SIZE` warping option and the value of the `-wm` option can also influence the shape of the processing chunk. Consequently, for a single (non-zero) value of the error threshold, the linear approximation might result in slightly different values in coordinate transformation, but all of them within the permitted error.

The error threshold (in source dataset pixels) can be controlled with the gdalwarp `-et` switch. If you want to compare a true pixel-by-pixel reprojection use `-et 0` which disables this approximator entirely.

Vertical transformation

While gdalwarp is most commonly used to perform coordinate transformations in the 2D space, it can also perform vertical transformations. Vertical transformations are automatically performed when the following two conditions are met:

- at least one of the source or target CRS has an explicit vertical CRS (as part of a compound CRS) or is a 3D (generally geographic) CRS, and
- the raster has a single band

This mode can also be forced by using the *-vshift* (this is essentially useful when the CRS involved are not explicitly 3D, but a transformation pipeline is specified with *-ct*), or disabled with *-novshift*.

When a vertical transformation is involved, typically a shift value read in a geoid grid will be applied. This may require such grid(s) to be installed, or PROJ networking capabilities to be enabled. Consult PROJ documentation for more details. In addition to a shift, the raster values may be multiplied by a factor to take into account vertical unit changes. In priority, the value returned by *GDALRasterBand::GetUnitType()* is used. The following values are currently recognized: `m`, `metre`, `metre`, `ft`, `foot`, `US survey foot`. If there is no defined unit type at the band level, the vertical unit of the source CRS is used. The vertical unit of the target CRS is also used to determine that conversion factor. The conversion factor may be overridden by setting the `MULT_FACTOR_VERTICAL_SHIFT` warping option with *-wo*. For example `-wo MULT_FACTOR_VERTICAL_SHIFT=1` to disable any vertical unit change.

Memory usage

Adding RAM will almost certainly increase the speed of **gdalwarp**. That's not at all the same as saying that it is worth it, or that the speed increase will be significant. Disks are the slowest part of the process. By default **gdalwarp** won't take much advantage of RAM. Using the flag *-wm 500* will operate on 500MB chunks at a time which is better than the default. The warp memory specified by *-wm* is shared among all threads, so it is especially beneficial to increase this value when running **gdalwarp** with *-wo NUM_THREADS* (or its equivalent *GDAL_NUM_THREADS*) greater than 1.

Increasing the I/O block cache size may also help. This can be done by setting the *GDAL_CACHEMAX* configuration like:

```
gdalwarp --config GDAL_CACHEMAX 500 -wm 500 ...
```

This uses 500MB of RAM for read/write caching, and 500MB of RAM for working buffers during the warp. Beyond that it is doubtful more memory will make a substantial difference.

Check CPU usage while **gdalwarp** is running. If it is substantially less than 100% then you know things are IO bound. Otherwise they are CPU bound. The `--debug` option may also provide useful information. For instance, after running the following:

```
gdalwarp --debug on abc.tif def.tif
```

a message like the following will be output:

```
GDAL: 224 block reads on 32 block band 1 of utm.tif
```

In this case it is saying that band 1 of `utm.tif` has 32 blocks, but that 224 block reads were done, implying that lots of data was having to be re-read, presumably because of a limited IO cache. You will also see messages like:

```
GDAL: GDALWarpKernel()::GWKNearestNoMasksByte()
Src=0,0,512x512 Dst=0,0,512x512
```

The Src/Dst windows show you the "chunk size" being used. In this case my whole image which is very small. If you find things are being broken into a lot of chunks increasing *-wm* may help somewhat.

But far more important than memory are ensuring you are going through an optimized path in the warper. If you ever see it reporting `GDALWarpKernel()::GWKGeneralCase()` you know things will be relatively slow. Basically, the fastest situations are nearest neighbour resampling on 8bit data without nodata or alpha masking in effect.

Compressed output

In some cases, the output of **gdalwarp** may be much larger than the original, even if the same compression algorithm is used. By default, **gdalwarp** operates on chunks that are not necessarily aligned with the boundaries of the blocks/tiles/strips of the output format, so this might cause repeated compression/decompression of partial blocks, leading to lost space in the output format.

The situation can be improved by using the `OPTIMIZE_SIZE` warping option (*-wo OPTIMIZE_SIZE=YES*), but note that depending on the source and target projections, it might also significantly slow down the warping process.

Another possibility is to use **gdalwarp** without compression and then follow up with **gdal_translate** with compression:

```
gdalwarp infile tempfile.tif ...options...
gdal_translate tempfile.tif outfile.tif -co compress=lzw ...etc.
```

Alternatively, you can use a VRT file as the output format of **gdalwarp**. The VRT file is just an XML file that will be created immediately. The **gdal_translate** operations will be of course a bit slower as it will do the real warping operation.

```
gdalwarp -of VRT infile tempfile.vrt ...options...
gdal_translate tempfile.vrt outfile.tif -co compress=lzw ...etc.
```

Frequently Asked Questions

Q1. Why does the quality of the output looks so bad (no anti-aliasing)?

Did you specify a resampling method, with *-r*, other than the default nearest neighbour?

Q2. Why do I get slightly different results whether the output dataset is tiled or not?

This is related to the fact that an approximate coordinate transformation is used by default to speed-up computation. If you want to get the same results whether the output is tiled or not, set *-et* to zero. Note, however, that this will only work for relatively small images; other factors can still result in different result. See following question (Q3).

Q3. Why do I observe artifacts, that look like resolution changes and are aligned with rectangular areas of the output raster, when warping sufficiently large rasters, particularly in areas where the reprojection involves significant deformation and only with non-nearest resampling ?

The warping engine operates on rectangular areas of the output dataset (generally aligned with tile boundaries for a compressed tile dataset).

During reprojection, a single source pixel does not generally correspond to a single output pixel. The resampling method must therefore properly account for this and compute a ratio between the number of source and target pixels in the horizontal (X) and vertical (Y) directions. These ratios are computed per warping chunk. This maximizes the local quality of the warping but has the downside of creating visual discontinuities between warping chunks.

If you favor a seamless result, you may manually specify the XSCALE and YSCALE warping options with *-wo*. The XSCALE (resp. YSCALE) value is the ratio expressing the resampling factor, i.e. the number of destination pixels per source pixel, along the horizontal (resp. vertical) axis. It equals to one for no resampling, is below one for downsampling, and above one for upsampling.

Examples

- Basic transformation:

```
gdalwarp -t_srs EPSG:4326 input.tif output.tif
```

- For instance, an eight bit spot scene stored in GeoTIFF with control points mapping the corners to lat/long could be warped to a UTM projection with a command like this:

```
gdalwarp -t_srs '+proj=utm +zone=11 +datum=WGS84' -overwrite raw_spot.tif utm11.tif
```

- For instance, the second channel of an ASTER image stored in HDF with control points mapping the corners to lat/long could be warped to a UTM projection with a command like this:

```
gdalwarp -overwrite HDF4_SDS:ASTER_L1B:"pg-PR1B0000-2002031402_100_001":2 \
    pg-PR1B0000-2002031402_100_001_2.tif
```

- To apply a cutline on a un-georeferenced image and clip from pixel (220,60) to pixel (1160,690):

```
gdalwarp -overwrite -to SRC_METHOD=NO_GEOTRANSFORM -to DST_METHOD=NO_GEOTRANSFORM \
    -te 220 60 1160 690 -cutline cutline.csv in.png out.tif
```

where cutline.csv content is like:

```
id,WKT
1,"POLYGON((....))"
```

- To transform a DEM from geoid elevations (using EGM96) to WGS84 ellipsoidal heights:

```
gdalwarp -overwrite in_dem.tif out_dem.tif -s_srs EPSG:4326+5773 -t_srs EPSG:4979
```

Return status code

The program returns status code 0 in case of success, and non-zero in case of error (non-blocking errors emitted as warnings are considered as a successful execution).

C API

This utility is also callable from C with *GDALWarp()*.

5.2.2.35 nearblack

Synopsis

```
Usage: nearblack [--help] [--long-usage] [--help-general]
                 [-of <output_format>] [--quiet] [-co <NAME>=<VALUE>]...
                 [-o <output_file>]
                 [[-white]|[-color <c1,c2,c3...cn>]...]
                 [-nb <non_black_pixels>] [-near <dist>] [-setalpha] [-setmask]
                 [-alg floodfill|twopasses]
                 <input_file>
```

Description

This utility will scan an image and try to set all pixels that are nearly or exactly black, white or one or more custom colors around the collar to black or white. This is often used to "fix up" lossy compressed air photos so that color pixels can be treated as transparent when mosaicing. The output format must use lossless compression if either alpha band or mask band is not set.

> **Tip**
>
> Equivalent in new "gdal" command line interface:
>
> See *gdal raster clean-collar*.

--help

Show this help message and exit

--help-general

Gives a brief usage message for the generic GDAL commandline options and exit.

-q, --quiet

Suppress progress messages and other non-error output.

-o <outfile>

The name of the output file to be created.

-of <format>

Select the output format. If not specified, the format is guessed from the extension. Use the short format name (GTiff for GeoTIFF for example).

-co <NAME>=<VALUE>

Passes a creation option to the output format driver. Multiple *-co* options may be listed. See *Raster drivers* format specific documentation for legal creation options for each format.

Only valid when creating a new file

-white

Search for nearly white (255) pixels instead of nearly black pixels.

-color <c1>,<c2>,<c3>...<cn>

Search for pixels near the specified color. May be specified multiple times. When -color is specified, the pixels that are considered as the collar are set to 0.

-near <dist>

Select how far from black, white or custom colors the pixel values can be and still considered near black, white or custom color. Defaults to 15.

-nb <non_black_pixels>

number of consecutive non-black pixels that can be encountered before the giving up search inwards. Defaults to 2.

-setalpha

Adds an alpha band if the output file is specified and the input file has 3 bands, or sets the alpha band of the output file if it is specified and the input file has 4 bands, or sets the alpha band of the input file if it has 4 bands and no output file is specified. The alpha band is set to 0 in the image collar and to 255 elsewhere.

-setmask

Adds a mask band to the output file, or adds a mask band to the input file if it does not already have one and no output file is specified. The mask band is set to 0 in the image collar and to 255 elsewhere.

-alg `twopasses|floodfill`

Added in version 3.8.

Selects the algorithm to apply.

`twopasses` uses a top-to-bottom pass followed by a bottom-to-top pass. This is the only algorithm implemented before GDAL 3.8. It may miss with concave areas. The algorithm processes the image one scanline at a time. A scan "in" is done from either end setting pixels to black or white until at least "non_black_pixels" pixels that are more than "dist" gray levels away from black, white or custom colors have been encountered at which point the scan stops. The nearly black, white or custom color pixels are set to black or white. The algorithm also scans from top to bottom and from bottom to top to identify indentations in the top or bottom.

`floodfill` (added in GDAL 3.8) uses the Flood Fill algorithm and will work with concave areas. It requires creating a temporary dataset and is slower than `twopasses`. When a non-zero value for *-nb* is used, `twopasses` is actually called as an initial step of `floodfill`.

<infile>

The input file. Any GDAL supported format, any number of bands, normally 8bit Byte bands.

The processing is all done in 8bit (Bytes).

If the output file is omitted, the processed results will be written back to the input file - which must support update.

Return status code

The program returns status code 0 in case of success, and non-zero in case of error (non-blocking errors emitted as warnings are considered as a successful execution).

C API

This utility is also callable from C with *GDALNearblack()*.

5.2.2.36 pct2rgb

Synopsis

```
pct2rgb [--help] [--help-general]
           [-of format] [-b band] [-rgba] [-pct palette_file] <source_file> <dest_file>
```

Description

This utility will convert a pseudo-color band on the input file into an output RGB file of the desired format.

> **Note**
>
> pct2rgb is a Python utility, and is only available if GDAL Python bindings are available.

--help

Show this help message and exit

--help-general

Gives a brief usage message for the generic GDAL commandline options and exit.

-of <format>

Select the output format. If not specified, the format is guessed from the extension. Use the short format name.

-b <band>

Band to convert to RGB, defaults to 1.

-rgba

Generate a RGBA file (instead of a RGB file by default).

-pct <palette_file>

Extract the color table from <palette_file> instead of getting it from <source_file>. Can be used to have a consistent color table for multiple files. The <palette_file> must be either a raster file in a GDAL supported format with a palette or a color file in a supported format (txt, qml, qlr).

<source_file>

The input file.

<dest_file>

The output RGB file that will be created.

The '-expand rgb|rgba' option of *gdal_translate* obsoletes that utility.

Return status code

The program returns status code 0 in case of success, and non-zero in case of error (non-blocking errors emitted as warnings are considered as a successful execution).

5.2.2.37 rgb2pct

Synopsis

```
rgb2pct [--help] [--help-general] [--creation-option OPTION]
           [-n colors | -pct palette_file] [-of format] <source_file> <dest_file>
```

Description

This utility will compute an optimal pseudo-color table for a given RGB image using a median cut algorithm on a downsampled RGB histogram. Then it converts the image into a pseudo-colored image using the color table. This conversion utilizes Floyd-Steinberg dithering (error diffusion) to maximize output image visual quality.

Note

rgb2pct is a Python utility, and is only available if GDAL Python bindings are available.

Tip

Equivalent in new "gdal" command line interface:

See *gdal raster rgb-to-palette*.

--help

Show this help message and exit

--help-general

Gives a brief usage message for the generic GDAL commandline options and exit.

-n <color>

Select the number of colors in the generated color table. Defaults to 256. Must be between 2 and 256.

--creation-option OPTION

Optional creation parameters for the GeoTIFF driver, for example "COMPRESS=LZW". Can be specified multiple times.

-pct <palette_file>

Extract the color table from <palette_file> instead of computing it. Can be used to have a consistent color table for multiple files. The <palette_file> must be either a raster file in a GDAL supported format with a palette or a color file in a supported format (txt, qml, qlr).

-of <format>

Select the output format. If not specified, the format is guessed from the extension. Use the short format name. Only output formats supporting pseudo-color tables should be used.

<source_file>

The input RGB file.

<dest_file>

The output pseudo-colored file that will be created.

Return status code

The program returns status code 0 in case of success, and non-zero in case of error (non-blocking errors emitted as warnings are considered as a successful execution).

Example

If it is desired to hand create the palette, likely the simplest text format is the GDAL VRT format. In the following example a VRT was created in a text editor with a small 4 color palette with the RGBA colors 238/238/238/255, 237/237/237/255, 236/236/236/255 and 229/229/229/255.

```
$ rgb2pct -pct palette.vrt rgb.tif pseudo-colored.tif
$ more < palette.vrt
<VRTDataset rasterXSize="226" rasterYSize="271">
    <VRTRasterBand dataType="Byte" band="1">
        <ColorInterp>Palette</ColorInterp>
        <ColorTable>
        <Entry c1="238" c2="238" c3="238" c4="255"/>
        <Entry c1="237" c2="237" c3="237" c4="255"/>
        <Entry c1="236" c2="236" c3="236" c4="255"/>
        <Entry c1="229" c2="229" c3="229" c4="255"/>
        </ColorTable>
    </VRTRasterBand>
</VRTDataset>
```

5.2.3 Multidimensional Raster programs

5.2.3.1 gdalmdiminfo

Synopsis

```
Usage: gdalmdiminfo [--help] [--long-usage] [--help-general]
                    [[-summary]|[-detailed]]
                    [-nopretty] [-array <array_name>] [-limit <number>]
                    [-oo <NAME>=<VALUE>]... [-if <format>]...
                    [-arrayoption <NAME>=<VALUE>]... [-stats]
                    <dataset_name>
```

Description

gdalmdiminfo program lists various information about a GDAL supported multidimensional raster dataset as JSON output. It follows the following JSON schema gdalmdiminfo_output.schema.json.

> **Tip**
>
> Equivalent in new "gdal" command line interface:
>
> See *gdal mdim info*.

The following command line parameters can appear in any order

--help

Show this help message and exit

--help-general

Gives a brief usage message for the generic GDAL commandline options and exit.

-detailed

Most verbose output. Report attribute data types and array values.

-nopretty

Outputs on a single line without any indentation.

-array <array_name>

Name of the array used to restrict the output to the specified array.

-limit <number>

Number of values in each dimension that is used to limit the display of array values. By default, unlimited. Only taken into account if used with -detailed.

-oo <NAME>=<VALUE>

Dataset open option (format specific). This option may be used several times.

-arrayoption <NAME>=<VALUE>

Option passed to *GDALGroup::GetMDArrayNames()* to filter reported arrays. Such option is format specific. Consult driver documentation. This option may be used several times.

-stats

Read and display array statistics. Force computation if no statistics are stored in an array.

Added in version 3.2.

-if <format>

Format/driver name to be attempted to open the input file(s). It is generally not necessary to specify it, but it can be used to skip automatic driver detection, when it fails to select the appropriate driver. This option can be repeated several times to specify several candidate drivers. Note that it does not force those drivers to open the dataset. In particular, some drivers have requirements on file extensions.

Added in version 3.2.

Return status code

The program returns status code 0 in case of success, and non-zero in case of error (non-blocking errors emitted as warnings are considered as a successful execution).

C API

This utility is also callable from C with *GDALMultiDimInfo()*.

Examples

Example 1: Display general structure

```
$ gdalmdiminfo netcdf-4d.nc
```

```
{
  "type": "group",
  "name": "/",
  "attributes": {
    "Conventions": "CF-1.5"
  },
  "dimensions": [
    {
      "name": "levelist",
      "full_name": "/levelist",
      "size": 2,
      "type": "VERTICAL",
      "indexing_variable": "/levelist"
    },
    {
      "name": "longitude",
      "full_name": "/longitude",
      "size": 10,
      "type": "HORIZONTAL_X",
      "direction": "EAST",
      "indexing_variable": "/longitude"
    },
    {
      "name": "latitude",
      "full_name": "/latitude",
      "size": 10,
      "type": "HORIZONTAL_Y",
      "direction": "NORTH",
      "indexing_variable": "/latitude"
    },
```

(continues on next page)

(continued from previous page)

```
    {
      "name": "time",
      "full_name": "/time",
        "size": 4,
      "type": "TEMPORAL",
      "indexing_variable": "/time"
      }
  ],
  "arrays": {
    "levelist": {
      "datatype": "Int32",
      "dimensions": [
          "/levelist"
        ],
      "attributes": {
        "long_name": "pressure_level"
      },
      "unit": "millibars"
    },
    "longitude": {
      "datatype": "Float32",
      "dimensions": [
        "/longitude"
      ],
      "attributes": {
        "standard_name": "longitude",
        "long_name": "longitude",
        "axis": "X"
      },
      "unit": "degrees_east"
    },
    "latitude": {
      "datatype": "Float32",
      "dimensions": [
        "/latitude"
      ],
      "attributes": {
        "standard_name": "latitude",
        "long_name": "latitude",
        "axis": "Y"
      },
      "unit": "degrees_north"
    },
    "time": {
      "datatype": "Float64",
      "dimensions": [
        "/time"
      ],
      "attributes": {
        "standard_name": "time",
        "calendar": "standard"
      },
```

(continues on next page)

(continued from previous page)

```
      "unit": "hours since 1900-01-01 00:00:00"
    },
    "t": {
      "datatype": "Int32",
      "dimensions": [
        "/time",
        "/levelist",
        "/latitude",
        "/longitude"
      ],
      "nodata_value": -32767
    }
  },
  "structural_info": {
    "NC_FORMAT": "CLASSIC"
  }
}
```

Example 2: Display detailed information about a given array

```
$ gdalmdiminfo netcdf-4d.nc -array t -detailed -limit 3
```

5.2.3.2 gdalmdimtranslate

Synopsis

```
Usage: gdalmdimtranslate [--help] [--long-usage] [--help-general]
                         [-if <format>]... [-of <output_format>]
                         [-co <NAME>=<VALUE>]...
                         [[-array <array_spec>]...]
                         [-arrayoption <NAME>=<VALUE>]...
                         [[-group <group_spec>]...]
                         [-subset <subset_spec>]...
                         [-scaleaxes <scaleaxes_spec>] [-strict]
                         [-oo <NAME>=<VALUE>]... [--quiet]
                         <src_dataset> <dst_dataset>
```

Description

gdalmdimtranslate program converts multidimensional raster between different formats, and/or can perform selective conversion of specific arrays and groups, and/or subsetting operations.

> **Tip**
>
> Equivalent in new "gdal" command line interface:
>
> See *gdal mdim convert*.

The following command line parameters can appear in any order.

--help

Show this help message and exit

--help-general

Gives a brief usage message for the generic GDAL commandline options and exit.

-q, --quiet

Suppress progress messages and other non-error output.

-if <format>

Format/driver name to be attempted to open the input file(s). It is generally not necessary to specify it, but it can be used to skip automatic driver detection, when it fails to select the appropriate driver. This option can be repeated several times to specify several candidate drivers. Note that it does not force those drivers to open the dataset. In particular, some drivers have requirements on file extensions.

Added in version 3.2.

-of <format>

Select the output format. This can be a format that supports multidimensional output (such as *NetCDF: Network Common Data Form*, *Multidimensional VRT*), or a "classic" 2D formats, if only one single 2D array results of the other specified conversion operations. When this option is not specified, the format is guessed when possible from the extension of the destination filename.

-co <NAME>=<VALUE>

Many formats have one or more optional creation options that can be used to control particulars about the file created.

The creation options available vary by format driver, and some simple formats have no creation options at all. A list of options supported for a format can be listed with the *--format* command line option but the documentation for the format is the definitive source of information on driver creation options. See *Raster drivers* format specific documentation for legal creation options for each format.

Array-level creation options may be passed by prefixing them with `ARRAY:`. See *`GDALGroup::CopyFrom()`* for further details regarding such options.

-array <array_spec>

Instead of converting the whole dataset, select one array, and possibly perform operations on it. This option can be specified several times to operate on different arrays.

<array_spec> may be just an array name, potentially using a fully qualified syntax (/group/subgroup/array_name). Or it can be a combination of options with the syntax: name={src_array_name}[,dstname={dst_array_name}][,resample=yes][,transpose=[{axis1},{axis2},...][,view={view_expr}]

The following options are processed in that order:

- `resample=yes` asks for the array to run through *`GDALMDArray::GetResampled()`*.
- **[{axis1},{axis2},...] is the argument of *`GDALMDArray::Transpose()`*.**
  For example, transpose=[1,0] switches the axis order of a 2D array. See *Example 5*.
- {view_expr} is the value of the *viewExpr* argument of *`GDALMDArray::GetView()`*. See *Example 4*.

When specifying a view_expr that performs a slicing or subsetting on a dimension, the equivalent operation will be applied to the corresponding indexing variable.

-arrayoption <NAME>=<VALUE>

Added in version 3.9.

Option passed to *`GDALGroup::GetMDArrayNames()`* to filter reported arrays. Such option is format specific. Consult driver documentation. This option may be used several times.

-group <group_spec>

Instead of converting the whole dataset, select one group, and possibly perform operations on it. This option can be specified several times to operate on different groups. If only one group is specified, its content will be copied directly to the target root group. If several ones are specified, they are copied under the target root group

<group_spec> may be just a group name, potentially using a fully qualified syntax (/group/subgroup/subsubgroup_name). Or it can be a combination of options with the syntax: name={src_group_name}[,dstname={dst_group_name}][,recursive=no]

-subset <subset_spec>

Performs a subsetting (trimming or slicing) operation along a dimension, provided that it is indexed by a 1D variable of numeric or string data type, and whose values are monotonically sorted. <subset_spec> follows exactly the OGC WCS 2.0 KVP encoding for subsetting.

That is dim_name(min_val,max_val) or dim_name(sliced_val) The first syntax will subset the dimension dim_name to values in the [min_val,max_val] range. The second syntax will slice the dimension dim_name to value sliced_val (and this dimension will be removed from the arrays that reference to it)

Using -subset is incompatible with specifying a *view* option in -array.

See *Example 2*.

-scaleaxes <scaleaxes_spec>

Applies a integral scale factor to one or several dimensions, that is extract 1 value every N values (without resampling).

<scaleaxes_spec> follows exactly the syntax of the KVP encoding of the SCALEAXES parameter of OGC WCS 2.0 Scaling Extension, but limited to integer scale factors.

That is <dim1_name>(<scale_factor>)[,<dim2_name>(<scale_factor>)]...

Using -scaleaxes is incompatible with specifying a *view* option in -array.

See *Example 3*.

-strict

By default, some failures during the translation are tolerated, such as not being able to write group attributes. When setting this option, such failures will cause the process to fail.

-oo <NAME>=<VALUE>

Added in version 3.4.

Source dataset open option (format specific)

<src_dataset>

The source dataset name.

<dst_dataset>

The destination file name.

Return status code

The program returns status code 0 in case of success, and non-zero in case of error (non-blocking errors emitted as warnings are considered as a successful execution).

C API

This utility is also callable from C with *GDALMultiDimTranslate()*.

Examples

Example 1: Convert a netCDF file to a multidimensional VRT file

```
gdalmdimtranslate in.nc out.vrt
```

Example 2: Extract a 2D slice of a time,Y,X array

```
gdalmdimtranslate in.nc out.tif -subset 'time("2010-01-01")' -array temperature
```

Example 3: Subsample along X and Y axis

```
gdalmdimtranslate in.nc out.nc -scaleaxes "X(2),Y(2)"
```

Example 4: Reorder the values of an array

Reorder the values of the time,Y,X array along the Y axis from top-to-bottom to bottom-to-top (or the reverse)

```
gdalmdimtranslate in.nc out.nc -array "name=temperature,view=[:,::-1,:]"
```

Example 5: Transpose an array that has X,Y,time dimension order to time,Y,X

```
gdalmdimtranslate in.nc out.nc -array "name=temperature,transpose=[2,1,0]"
```

5.2.4 Vector programs

5.2.4.1 Common options for vector programs

All GDAL OGR command line programs support the following common options.

--version

Report the version of GDAL and exit.

--build

Report detailed information about GDAL in use.

--formats

List all vector formats supported by this GDAL build (read-only and read-write) and exit. The format support is indicated as follows:

- `ro` is read-only driver
- `rw` is read or write (i.e. supports *GDALDriver::CreateCopy()*)
- `rw+` is read, write and update (i.e. supports *GDALDriver::Create()*)
- A `v` is appended for formats supporting virtual IO (`/vsimem`, `/vsigzip`, `/vsizip`, etc).
- A `s` is appended for formats supporting subdatasets.

The order in which drivers are listed is the one in which they are registered, which determines the order in which they are successively probed when opening a dataset. Most of the time, this order does not matter, but in some situations, several drivers may recognize the same file. The `-if` option of some utilities can be specified to restrict opening the dataset with a subset of drivers (generally one). Note that it does not force those drivers to open the dataset. In particular, some drivers have requirements on file extensions. Alternatively, the *GDAL_SKIP* configuration option can also be used to exclude one or several drivers.

--format <format>

List detailed information about a single format driver. The format should be the short name reported in the *--formats* list, such as GML.

--formats

List all drivers. Can be combined with `-json` switch of **ogrinfo** of since GDAL 3.10

--optfile <filename>

Read the named file and substitute the contents into the command line options list. Lines beginning with # will be ignored. Multi-word arguments may be kept together with double quotes.

--config <key> <value>

Sets the named configuration keyword to the given value, as opposed to setting them as environment variables. Some common configuration keywords are *SHAPE_ENCODING* (force shapefile driver to read DBF files with the given character encoding) and *CPL_TMPDIR* (define the location of temporary files). Individual drivers may be influenced by other *configuration options*.

--debug <value>

Control what debugging messages are emitted. A value of ON will enable all debug messages. A value of OFF will disable all debug messages. Otherwise, a debug message will be emitted if its category appears somewhere in the value string.

--help-general

Gives a brief usage message for the generic GDAL OGR command line options and exit.

5.2.4.2 ogrinfo

Synopsis

```
Usage: ogrinfo [--help] [--long-usage] [--help-general]

```

Description

The **ogrinfo** program lists various information about an OGR-supported data source to stdout (the terminal). By executing SQL statements it is also possible to edit data.

Tip

Equivalent in new "gdal" command line interface:

See *gdal vector info*.

--help

Show this help message and exit

--help-general

Gives a brief usage message for the generic GDAL commandline options and exit.

-if <format>

Format/driver name to be attempted to open the input file(s). It is generally not necessary to specify it, but it can be used to skip automatic driver detection, when it fails to select the appropriate driver. This option can be repeated several times to specify several candidate drivers. Note that it does not force those drivers to open the dataset. In particular, some drivers have requirements on file extensions.

Added in version 3.2.

-json

Display the output in json format, conforming to the ogrinfo_output.schema.json ogrinfo_output.schema.json schema.

Added in version 3.7.

-ro

Open the data source in read-only mode.

-al

List all layers (used instead of having to give layer names as arguments). In the default text output, this also enables listing all features, which can be disabled with *-so*. In JSON output, -al is implicit, but listing of features must be explicitly enabled with *-features*.

-rl

Enable random layer reading mode, i.e. iterate over features in the order they are found in the dataset, and not layer per layer. This can be significantly faster for some formats (for example OSM, GMLAS). -rl cannot be used with -sql.

-so

Summary Only: suppress listing of individual features and show only summary information like projection, schema, feature count and extents. In JSON output, -so is implicit and listing of features can be enabled with *-features*.

-features

Enable listing of features. This has the opposite effect of *-so*.

This option should be used with caution if using the library function *GDALVectorInfo()* and/or *-json*, as the whole output of ogrinfo will be built in memory. Consequently, when used on a large collection of features, RAM may be exhausted.

Added in version 3.7.

-limit <nb_features>

Added in version 3.9.

Limit the number of features per layer.

-q

Quiet verbose reporting of various information, including coordinate system, layer schema, extents, and feature count.

-where <restricted_where>

An attribute query in a restricted form of the queries used in the SQL *WHERE* statement. Only features matching the attribute query will be reported. The @<filename> syntax can be used to indicate that the content is in the pointed filename.

Example of -where and quoting:

```
-where "\"Corner Point Identifier\" LIKE '%__00_00'"
```

Note: -dialect is ignored with -where. Use -sql instead of -where if you want to use -dialect.

-sql <statement>|@<filename>

Execute the indicated SQL statement and return the result. The @<filename> syntax can be used to indicate that the content is in the pointed filename (e.g @my_select.txt where my_select.txt is a file in the current directory). Data can also be edited with SQL INSERT, UPDATE, DELETE, DROP TABLE, ALTER TABLE etc. Editing capabilities depend on the selected dialect with *-dialect*.

-dialect <dialect>

SQL dialect. In some cases can be used to use (unoptimized) *OGR SQL dialect* instead of the native SQL of an RDBMS by passing the OGRSQL dialect value. The *SQL SQLite dialect* can be selected with the SQLITE and INDIRECT_SQLITE dialect values, and this can be used with any datasource. Note: -dialect is ignored with -where. Use -sql instead of -where if you want to use -dialect.

-spat <xmin> <ymin> <xmax> <ymax>

The area of interest. Only features within the rectangle will be reported.

-geomfield <field>

Name of the geometry field on which the spatial filter operates.

-fid <fid>

If provided, only the feature with this feature id will be reported. Operates exclusive of the spatial or attribute queries. Note: if you want to select several features based on their feature id, you can also use the fact the 'fid' is a special field recognized by OGR SQL. So, *-where "fid in (1,3,5)"* would select features 1, 3 and 5.

-fields=YES|NO

If set to NO, the feature dump will not display field values. Default value is YES.

-fielddomain <domain_name>

Added in version 3.3.

Display details about a field domain.

-geom=YES|NO|SUMMARY|WKT|ISO_WKT

If set to NO, the feature dump will not display the geometry. If set to SUMMARY, only a summary of the geometry will be displayed. If set to YES or ISO_WKT, the geometry will be reported in full OGC WKT format. If set to WKT the geometry will be reported in legacy WKT. Default value is YES.

-oo <NAME>=<VALUE>

Dataset open option (format specific).

If a driver supports the OGR_SCHEMA open option, it can be used to partially or completely override the auto-detected schema (i.e. which fields are read, with which types, subtypes, length, precision etc.) of the dataset.

The value of this option is a JSON string or a path to a JSON file that complies with the OGR_SCHEMA open option schema definition

-nomd

Suppress metadata printing. Some datasets may contain a lot of metadata strings.

-listmdd

List all metadata domains available for the dataset.

-mdd <domain>

Report metadata for the specified domain. `all` can be used to report metadata in all domains.

-nocount

Suppress feature count printing.

-noextent

Suppress spatial extent printing.

-extent3D

Added in version 3.9.

Request a 3D extent to be reported (the default is 2D only). Note that this operation might be slower than requesting the 2D extent, depending on format and driver capabilities.

-nogeomtype

Suppress layer geometry type printing.

Added in version 3.1.

--formats

List all vector formats supported by this GDAL build (read-only and read-write) and exit. The format support is indicated as follows:

- `ro` is read-only driver
- `rw` is read or write (i.e. supports *GDALDriver::CreateCopy()*)
- `rw+` is read, write and update (i.e. supports *GDALDriver::Create()*)
- A `v` is appended for formats supporting virtual IO (`/vsimem`, `/vsigzip`, `/vsizip`, etc).
- A `s` is appended for formats supporting subdatasets.

The order in which drivers are listed is the one in which they are registered, which determines the order in which they are successively probed when opening a dataset. Most of the time, this order does not matter, but in some situations, several drivers may recognize the same file. The `-if` option of some utilities can be specified to restrict opening the dataset with a subset of drivers (generally one). Note that it does not force those drivers to open the dataset. In particular, some drivers have requirements on file extensions. Alternatively, the *GDAL_SKIP* configuration option can also be used to exclude one or several drivers.

-wkt_format <format>

The WKT format used to display the SRS. Currently supported values for the `format` are:

`WKT1`

`WKT2` (latest WKT version, currently *WKT2_2018*)

`WKT2_2015`

`WKT2_2018`

Added in version 3.0.0.

<datasource_name>

The data source to open. May be a filename, directory or other virtual name. See the OGR Vector Formats list for supported datasources.

<layer>

One or more layer names may be reported. If no layer names are passed then ogrinfo will report a list of available layers (and their layer wide geometry type). If layer name(s) are given then their extents, coordinate system, feature count, geometry type, schema and all features matching query parameters will be reported to the terminal. If no query parameters are provided, all features are reported.

Geometries are reported in OGC WKT format.

Return status code

The program returns status code 0 in case of success, and non-zero in case of error (non-blocking errors emitted as warnings are considered as a successful execution).

C API

This utility is also callable from C with *GDALVectorInfo()*.

Added in version 3.7.

Examples

Example 1: Reporting the names of the layers in a NTF file

```
$ ogrinfo wrk/SHETLAND_ISLANDS.NTF

INFO: Open of `wrk/SHETLAND_ISLANDS.NTF'
using driver `UK .NTF' successful.
1: BL2000_LINK (Line String)
2: BL2000_POLY (None)
3: BL2000_COLLECTIONS (None)
4: FEATURE_CLASSES (None)
```

Example 2: Retrieving a summary (-so) of a layer without showing details about every feature

```
$ ogrinfo \
  -so \
  natural_earth_vector.gpkg \
  ne_10m_admin_0_antarctic_claim_limit_lines

INFO: Open of `natural_earth_vector.gpkg'
     using driver `GPKG' successful.

Layer name: ne_10m_admin_0_antarctic_claim_limit_lines
Geometry: Line String
Feature Count: 23
Extent: (-150.000000, -90.000000) - (160.100000, -60.000000)
Layer SRS WKT:
GEOGCS["WGS 84",
    DATUM["WGS_1984",
```

Example 4: Using -q and an attribute query to restrict the output to certain features in a layer

```
$ ogrinfo -q -ro \
    -where 'GLOBAL_LINK_ID=185878' \
    wrk/SHETLAND_ISLANDS.NTF BL2000_LINK

Layer name: BL2000_LINK
OGRFeature(BL2000_LINK):2
  LINE_ID (Integer) = 2
  GEOM_ID (Integer) = 2
  FEAT_CODE (String) = (null)
  GLOBAL_LINK_ID (Integer) = 185878
  TILE_REF (String) = SHETLAND I
  LINESTRING (419832.100 1069046.300,419820.100 1069043.800,...
```

Example 5: Updating a value of an attribute in a shapefile with SQL by using the SQLite dialect

```
ogrinfo test.shp -dialect sqlite -sql "update test set attr='bar' where attr='foo'"
```

Example 6: Adding a column to an input file

```
ogrinfo input.shp -sql "ALTER TABLE input ADD fieldX float"
```

Example 7: Performing a SQL query without an input file

Sometimes there is no input file involved in a calculation. In such cases one may use the `:memory:` input file which is a in-memory empty SQLite file (and the SQLite SQL dialect will be implicitly used).

```
ogrinfo :memory: -sql "SELECT ST_Buffer(ST_GeomFromText('POINT(0 0)'), 1)"
```

5.2.4.3 ogr2ogr

Synopsis

```
Usage: ogr2ogr [--help] [--long-usage] [--help-general]

                [[-skipfailures]|[-gt <n>|unlimited]]
                [-limit <nb_features>] [-ds_transaction] [-mo <NAME>=<VALUE>]...
                [-nomd]
```

Description

ogr2ogr can be used to convert simple features data between file formats. It can also perform various operations during the process, such as spatial or attribute selection, reducing the set of attributes, setting the output coordinate system or even reprojecting the features during translation.

Tip

Equivalent in new "gdal" command line interface:

- *gdal vector clip* for spatial subsetting
- *gdal vector convert* for format translation

- *gdal vector explode-collections* to explode geometries of type collection
- *gdal vector make-valid* to fix geometry validity
- *gdal vector reproject* for reprojection
- *gdal vector segmentize* to segmentize geometries
- *gdal vector select* to select a subset of fields
- *gdal vector set-field-type* to change the type of an attribute field
- *gdal vector set-geom-type* to change the type of a geometry field
- *gdal vector simplify* to simplify geometries
- *gdal vector sql* to run SQL query

--help

Show this help message and exit

--help-general

Gives a brief usage message for the generic GDAL commandline options and exit.

-q, --quiet

Suppress progress messages and other non-error output.

-if <format>

Format/driver name to be attempted to open the input file(s). It is generally not necessary to specify it, but it can be used to skip automatic driver detection, when it fails to select the appropriate driver. This option can be repeated several times to specify several candidate drivers. Note that it does not force those drivers to open the dataset. In particular, some drivers have requirements on file extensions.

Added in version 3.2.

-of <format_name>, **-f** <format_name>

Output file format name, e.g. `ESRI Shapefile`, `MapInfo File`, `PostgreSQL`. If not specified, the format is guessed from the extension.

-append

Append to existing layer instead of creating new. This option also enables `-update`.

-upsert

Added in version 3.6.

Variant of `-append` where the *`OGRLayer::UpsertFeature()`* operation is used to insert or update features instead of appending with *`OGRLayer::CreateFeature()`*.

This is currently implemented only in a few drivers: *GPKG -- GeoPackage vector*, *Elasticsearch: Geographically Encoded Objects for Elasticsearch* and *MongoDBv3* (drivers that implement upsert expose the *`GDAL_DCAP_UPSERT`* capability).

The upsert operation uses the FID of the input feature, when it is set and is a "significant" (that is the FID column name is not the empty string), as the key to update existing features. It is crucial to make sure that the FID in the source and target layers are consistent.

For the GPKG driver, it is also possible to upsert features whose FID is unset or non-significant (`-unsetFid` can be used to ignore the FID from the source feature), when there is a UNIQUE column that is not the integer primary key.

-overwrite

Delete the output layer and recreate it empty

-update

Open existing output datasource in update mode rather than trying to create a new one

-select <field_list>

Comma-delimited list of fields from input layer to copy to the new layer.

Starting with GDAL 3.9, field names with spaces, commas or double-quote should be surrounded with a starting and ending double-quote character, and double-quote characters in a field name should be escaped with backslash.

Depending on the shell used, this might require further quoting. For example, to select `regular_field`, `a_field_with space, and comma` and `a field with " double quote` with a Unix shell:

```
-select "regular_field,\"a_field_with space, and comma\",\"a field with \\\" double␣
↪quote\""
```

A field is only selected once, even if mentioned several times in the list and if the input layer has duplicate field names.

Geometry fields can also be specified in the list.

All fields are selected when -select is not specified. Specifying the empty string can be used to disable selecting any attribute field, and only keep geometries.

Note this setting cannot be used together with `-append`. To control the selection of fields when appending to a layer, use `-fieldmap` or `-sql`.

-progress

Display progress on terminal. Only works if input layers have the "fast feature count" capability.

-sql <sql_statement>|@<filename>

SQL statement to execute. The resulting table/layer will be saved to the output. The `@filename` syntax can be used to indicate that the content is in the pointed filename. (Cannot be used with *-spat_srs*.)

-dialect <dialect>

SQL dialect. In some cases can be used to use the (unoptimized) *OGR SQL dialect* instead of the native SQL of an RDBMS by passing the `OGRSQL` dialect value. The *SQL SQLite dialect* dialect can be chosen with the `SQLITE` and `INDIRECT_SQLITE` dialect values, and this can be used with any datasource. (*-dialect* is ignored with *-where*. Use *-sql* instead.)

-where <restricted_where>|@<filename>

Attribute query (like SQL WHERE). The `@filename` syntax can be used to indicate that the content is in the pointed filename. (*-dialect* is ignored with *-where*. Use *-sql* instead.)

-skipfailures

Continue after a failure, skipping the failed feature. Note that this option overrides the value of *-gt* to 1, which may cause severe slowdown when inserting into databases.

-spat <xmin> <ymin> <xmax> <ymax>

spatial query extents, in the SRS of the source layer(s) (or the one specified with `-spat_srs`). Only features whose geometry intersects the extents will be selected. The geometries will not be clipped unless `-clipsrc` is specified.

-spat_srs <srs_def>

Override spatial filter SRS. (Cannot be used with *-sql*.)

-geomfield <field>

Name of the geometry field on which the spatial filter operates on.

-dsco <NAME>=<VALUE>

Dataset creation option (format specific)

-lco <NAME>=<VALUE>

Layer creation option (format specific)

-nln <name>

Assign an alternate name to the new layer

-nlt <type>

Define the geometry type for the created layer. One of NONE, GEOMETRY, POINT, LINESTRING, POLYGON, GEOMETRYCOLLECTION, MULTIPOINT, MULTIPOLYGON, MULTILINESTRING, CIRCULARSTRING, COMPOUNDCURVE, CURVEPOLYGON, MULTICURVE, and MULTISURFACE non-linear geometry types. Add Z, M, or ZM to the type name to specify coordinates with elevation, measure, or elevation and measure. PROMOTE_TO_MULTI can be used to automatically promote layers that mix polygon or multipolygons to multipolygons, and layers that mix linestrings or multilinestrings to multilinestrings. Can be useful when converting shapefiles to PostGIS and other target drivers that implement strict checks for geometry types. CONVERT_TO_LINEAR can be used to to convert non-linear geometry types into linear geometry types by approximating them, and CONVERT_TO_CURVE to promote a non-linear type to its generalized curve type (POLYGON to CURVEPOLYGON, MULTIPOLYGON to MULTISURFACE, LINESTRING to COMPOUNDCURVE, MULTILINESTRING to MULTICURVE). Starting with version 2.1 the type can be defined as measured ("25D" remains as an alias for single "Z"). Some forced geometry conversions may result in invalid geometries, for example when forcing conversion of multi-part multipolygons with -nlt POLYGON, the resulting polygon will break the Simple Features rules.

Starting with GDAL 3.0.5, -nlt CONVERT_TO_LINEAR and -nlt PROMOTE_TO_MULTI can be used simultaneously.

-dim <val>

Force the coordinate dimension to val (valid values are XY, XYZ, XYM, and XYZM - for backwards compatibility 2 is an alias for XY and 3 is an alias for XYZ). This affects both the layer geometry type, and feature geometries. The value can be set to layer_dim to instruct feature geometries to be promoted to the coordinate dimension declared by the layer.

-a_srs <srs_def>

Assign an output SRS, but without reprojecting (use *-t_srs* to reproject)

The coordinate reference systems that can be passed are anything supported by the *OGRSpatialReference::SetFromUserInput()* call, which includes EPSG Projected, Geographic or Compound CRS (i.e. EPSG:4296), a well known text (WKT) CRS definition, PROJ.4 declarations, or the name of a .prj file containing a WKT CRS definition.

-a_coord_epoch <epoch>

Added in version 3.4.

Assign a coordinate epoch, linked with the output SRS. Useful when the output SRS is a dynamic CRS. Only taken into account if *-a_srs* is used.

-t_srs <srs_def>

Reproject/transform to this SRS on output, and assign it as output SRS.

A source SRS must be available for reprojection to occur. The source SRS will be by default the one found in the source layer when it is available, or as overridden by the user with *-s_srs*

The coordinate reference systems that can be passed are anything supported by the *OGRSpatialReference::SetFromUserInput()* call, which includes EPSG Projected, Geographic or

Compound CRS (i.e. EPSG:4296), a well known text (WKT) CRS definition, PROJ.4 declarations, or the name of a .prj file containing a WKT CRS definition.

-t_coord_epoch <epoch>

Added in version 3.4.

Assign a coordinate epoch, linked with the output SRS. Useful when the output SRS is a dynamic CRS. Only taken into account if *-t_srs* is used. It is also mutually exclusive with *-a_coord_epoch*.

Before PROJ 9.4, *-s_coord_epoch* and *-t_coord_epoch* were mutually exclusive, due to lack of support for transformations between two dynamic CRS.

-s_srs <srs_def>

Override source SRS. If not specified the SRS found in the input layer will be used. This option has only an effect if used together with *-t_srs* to reproject.

The coordinate reference systems that can be passed are anything supported by the *OGRSpatialReference::SetFromUserInput()* call, which includes EPSG Projected, Geographic or Compound CRS (i.e. EPSG:4296), a well known text (WKT) CRS definition, PROJ.4 declarations, or the name of a .prj file containing a WKT CRS definition.

-xyRes "<val>[m|mm|deg]"

Added in version 3.9.

Set/override the geometry X/Y coordinate resolution. If only a numeric value is specified, it is assumed to be expressed in the units of the target SRS. The m, mm or deg suffixes can be specified to indicate that the value must be interpreted as being in meter, millimeter or degree.

When specifying this option, the *OGRGeometry::SetPrecision()* method is run on geometries (that are not curves) before passing them to the output driver, to avoid generating invalid geometries due to the potentially reduced precision (unless the *OGR_APPLY_GEOM_SET_PRECISION* configuration option is set to NO)

If neither this option nor *-unsetCoordPrecision* are specified, the coordinate resolution of the source layer, if available, is used.

-zRes "<val>[m|mm]"

Added in version 3.9.

Set/override the geometry Z coordinate resolution. If only a numeric value is specified, it is assumed to be expressed in the units of the target SRS. The m or mm suffixes can be specified to indicate that the value must be interpreted as being in meter or millimeter. If neither this option nor *-unsetCoordPrecision* are specified, the coordinate resolution of the source layer, if available, is used.

-mRes <val>

Added in version 3.9.

Set/override the geometry M coordinate resolution. If neither this option nor *-unsetCoordPrecision* are specified, the coordinate resolution of the source layer, if available, is used.

-unsetCoordPrecision

Added in version 3.9.

Prevent the geometry coordinate resolution from being set on target layer(s).

-s_coord_epoch <epoch>

Added in version 3.4.

Assign a coordinate epoch, linked with the source SRS. Useful when the source SRS is a dynamic CRS. Only taken into account if *-s_srs* is used.

Before PROJ 9.4, *-s_coord_epoch* and *-t_coord_epoch* were mutually exclusive, due to lack of support for transformations between two dynamic CRS.

-ct <string>

Added in version 3.0.

A PROJ string (single step operation or multiple step string starting with +proj=pipeline), a WKT2 string describing a CoordinateOperation, or a urn:ogc:def:coordinateOperation:EPSG::XXXX URN overriding the default transformation from the source to the target CRS.

It must take into account the axis order of the source and target CRS, that is typically include a `step proj=axisswap order=2,1` at the beginning of the pipeline if the source CRS has northing/easting axis order, and/or at the end of the pipeline if the target CRS has northing/easting axis order.

-ct_opt <NAME>=<VALUE>

Added in version 3.11.

Specify a coordinate operation option that influences how PROJ selects coordinate operations when `-ct` is *not* set.

The following options are available:

- `ONLY_BEST``=``YES/NO`. By default (at least in the PROJ 9.x series), PROJ may use coordinate operations that are not the "best" if resources (typically grids) needed to use them are missing. It will then fallback to other coordinate operations that have a lesser accuracy, for example using Helmert transformations, or in the absence of such operations, to ones with potential very rough accuracy, using "ballpark" transformations (see https://proj.org/glossary.html). When calling this method with YES, PROJ will only consider the "best" operation, and error out (at Transform() time) if they cannot be used. This method may be used together with `ALLOW_BALLPARK``=``NO` to only allow best operations that have a known accuracy. Note that this method has no effect on PROJ versions before 9.2. The default value for this option can be also set with the `PROJ_ONLY_BEST_DEFAULT` environment variable, or with the `only_best_default` setting of proj.ini. Setting ONLY_BEST=YES/NO overrides such default value.
- `ALLOW_BALLPARK``=``YES/NO`. Whether ballpark coordinate operations are allowed. Default is YES.
- `WARN_ABOUT_DIFFERENT_COORD_OP``=``YES/NO`. Can be set to NO to avoid GDAL warning when different coordinate operations are used to transform the different geometries of the dataset (or part of the same geometry). Default is YES.

-preserve_fid

Use the FID of the source features instead of letting the output driver automatically assign a new one (for formats that require a FID). If not in append mode, this behavior is the default if the output driver has a FID layer creation option, in which case the name of the source FID column will be used and source feature IDs will be attempted to be preserved. This behavior can be disabled by setting `-unsetFid`. This option is not compatible with `-explodecollections`.

-fid <fid>

If provided, only the feature with the specified feature id will be processed. Operates exclusive of the spatial or attribute queries. Note: if you want to select several features based on their feature id, you can also use the fact the 'fid' is a special field recognized by OGR SQL. So, *-where "fid in (1,3,5)"* would select features 1, 3 and 5.

-limit <nb_features>

Limit the number of features per layer.

-oo <NAME>=<VALUE>

Dataset open option (format specific).

If a driver supports the `OGR_SCHEMA` open option, it can be used to partially or completely override the auto-detected schema (i.e. which fields are read, with which types, subtypes, length, precision etc.) of the dataset.

The value of this option is a JSON string or a path to a JSON file that complies with the OGR_SCHEMA open option schema definition

-doo <NAME>=<VALUE>

Destination dataset open option (format specific), only valid in -update mode.

-gt <n>

Group n features per transaction (default 100 000). Increase the value for better performance when writing into DBMS drivers that have transaction support. n can be set to unlimited to load the data into a single transaction.

-ds_transaction

Force the use of a dataset level transaction (for drivers that support such mechanism), especially for drivers such as FileGDB that only support dataset level transaction in emulation mode.

-clipsrc [<xmin> <ymin> <xmax> <ymax>]|WKT|<datasource>|spat_extent

Clip geometries (before potential reprojection) to one of the following:

- the specified bounding box (expressed in source SRS)
- a WKT geometry (POLYGON or MULTIPOLYGON expressed in source SRS)
- one or more geometries selected from a datasource
- the spatial extent of the -spat option if you use the spat_extent keyword.

When specifying a datasource, you will generally want to use -clipsrc in combination of the -clipsrclayer, -clipsrcwhere or -clipsrcsql options.

-clipsrcsql <sql_statement>

Select desired geometries from the source clip datasource using an SQL query.

-clipsrclayer <layername>

Select the named layer from the source clip datasource.

-clipsrcwhere <expression>

Restrict desired geometries from the source clip layer based on an attribute query.

-clipdst [<xmin> <ymin> <xmax> <ymax>]|<WKT>|<datasource>

Clip geometries (after potential reprojection) to one of the following:

- the specified bounding box (expressed in destination SRS)
- a WKT geometry (POLYGON or MULTIPOLYGON expressed in destination SRS)
- one or more geometries selected from a datasource

When specifying a datasource, you will generally want to use -clipdst in combination with the -clipdstlayer, -clipdstwhere or -clipdstsql options.

-clipdstsql <sql_statement>

Select desired geometries from the destination clip datasource using an SQL query.

-clipdstlayer <layername>

Select the named layer from the destination clip datasource.

-clipdstwhere <expression>

Restrict desired geometries from the destination clip layer based on an attribute query.

-wrapdateline

Split geometries crossing the dateline meridian (long. = +/- 180deg)

-datelineoffset

Offset from dateline in degrees (default long. = +/- 10deg, geometries within 170deg to -170deg will be split)

-simplify <tolerance>

Distance tolerance for simplification. Note: the algorithm used preserves topology per feature, in particular for polygon geometries, but not for a whole layer.

The specified value of this option is the tolerance used to merge consecutive points of the output geometry using the *OGRGeometry::SimplifyPreserveTopology()* method The unit of the distance is in georeferenced units of the source vector dataset. This option is applied before the reprojection implied by *-t_srs*

-segmentize <max_dist>

The specified value of this option is the maximum distance between two consecutive points of the output geometry before intermediate points are added. The unit of the distance is georeferenced units of the source layer. This option is applied before the reprojection implied by *-t_srs*

-makevalid

Run the *OGRGeometry::MakeValid()* operation, followed by *OGRGeometryFactory::removeLowerDimensionSubGeoms()*, on geometries to ensure they are valid regarding the rules of the Simple Features specification.

Added in version 3.1: (requires GEOS)

-skipinvalid

Run the *OGRGeometry::IsValid()* operation on geometries to check if they are valid regarding the rules of the Simple Features specification. If they are not, the feature is skipped. This check is done after all other geometry operations.

Added in version 3.10: (requires GEOS)

-fieldTypeToString All|<type1>[,<type2>]...

Converts any field of the specified type to a field of type string in the destination layer. Valid types are : Integer, Integer64, Real, String, Date, Time, DateTime, Binary, IntegerList, Integer64List, RealList, StringList. Special value All can be used to convert all fields to strings. This is an alternate way to using the CAST operator of OGR SQL, that may avoid typing a long SQL query. Note that this does not influence the field types used by the source driver, and is only an afterwards conversion. Also note that this option is without effects on fields whose presence and type is hard-coded in the output driver (e.g KML, GPX). For an alternative way to manipulate field types earlier in the process while they are read from the input dataset see *-oo* OGR_SCHEMA (only available for a limited set of formats).

-mapFieldType {<srctype>|All=<dsttype>[,<srctype2>=<dsttype2>]...}

Converts any field of the specified type to another type. Valid types are : Integer, Integer64, Real, String, Date, Time, DateTime, Binary, IntegerList, Integer64List, RealList, StringList. Types can also include subtype between parenthesis, such as Integer(Boolean), Real(Float32), ... Special value All can be used to convert all fields to another type. This is an alternate way to using the CAST operator of OGR SQL, that may avoid typing a long SQL query. This is a generalization of -fieldTypeToString. Note that this does not influence the field types used by the source driver, and is only an afterwards conversion. Also note that this option is without effects on fields whose presence and type is hard-coded in the output driver (e.g KML, GPX). For an alternative way to manipulate field types earlier in the process while they are read from the input dataset see *-oo* OGR_SCHEMA (only available for a limited set of formats).

-dateTimeTo {UTC|UTC(+|-)<HH>|UTC(+|-)<HH>:<MM>}

Added in version 3.7.

Converts date time values from the timezone specified in the source value to the target timezone expressed with *-dateTimeTo*. Datetime whose timezone is unknown or localtime are not modified.

HH must be in the [0,14] range and MM=00, 15, 30 or 45.

-unsetFieldWidth

Set field width and precision to 0.

-splitlistfields

Split fields of type StringList, RealList or IntegerList into as many fields of type String, Real or Integer as necessary.

-maxsubfields <val>

To be combined with `-splitlistfields` to limit the number of subfields created for each split field.

-explodecollections

Produce one feature for each geometry in any kind of geometry collection in the source file, applied after any `-sql` option. This options is not compatible with `-preserve_fid` but `-sql "SELECT fid AS original_fid, * FROM ..."` can be used to store the original FID if needed.

-zfield <field_name>

Uses the specified field to fill the Z coordinate of geometries.

-gcp <ungeoref_x> <ungeoref_y> <georef_x> <georef_y> [<elevation>]

Use the indicated ground control point to compute a coordinate transformation. The transformation method can be selected by specifying the *-order* or *-tps* options. Note that unlike raster tools such as gdal_edit or gdal_translate, GCPs are not added to the output dataset. This option may be provided multiple times to provide a set of GCPs (at least 2 GCPs are needed).

-order <n>

Order of polynomial used for warping (1 to 3). The default is to select a polynomial order based on the number of GCPs.

-tps

Force use of thin plate spline transformer based on available GCPs.

-fieldmap

Specifies the list of field indexes to be copied from the source to the destination. The (n)th value specified in the list is the index of the field in the target layer definition in which the n(th) field of the source layer must be copied. Index count starts at zero. To omit a field, specify a value of -1. There must be exactly as many values in the list as the count of the fields in the source layer. We can use the 'identity' setting to specify that the fields should be transferred by using the same order. This setting should be used along with the `-append` setting.

-addfields

This is a specialized version of `-append`. Contrary to `-append`, `-addfields` has the effect of adding, to existing target layers, the new fields found in source layers. This option is useful when merging files that have non-strictly identical structures. This might not work for output formats that don't support adding fields to existing non-empty layers. Note that if you plan to use -addfields, you may need to combine it with -forceNullable, including for the initial import.

-relaxedFieldNameMatch

Do field name matching between source and existing target layer in a more relaxed way if the target driver has an implementation for it.

-forceNullable

Do not propagate not-nullable constraints to target layer if they exist in source layer.

-unsetDefault

Do not propagate default field values to target layer if they exist in source layer.

-unsetFid

Can be specified to prevent the name of the source FID column and source feature IDs from being reused for the target layer. This option can for example be useful if selecting source features with a ORDER BY clause.

-emptyStrAsNull

Added in version 3.3.

Treat empty string values as null.

-resolveDomains

Added in version 3.3.

When this is specified, any selected field that is linked to a coded field domain will be accompanied by an additional field (`{dstfield}_resolved`), that will contain the description of the coded value.

-nomd

To disable copying of metadata from source dataset and layers into target dataset and layers, when supported by output driver.

-mo `<META-TAG>=<VALUE>`

Passes a metadata key and value to set on the output dataset, when supported by output driver.

-noNativeData

To disable copying of native data, i.e. details of source format not captured by OGR abstraction, that are otherwise preserved by some drivers (like GeoJSON) when converting to same format.

<dst_dataset_name>

Output dataset name.

<src_dataset_name>

Source dataset name.

<layer_name>

One or more source layer names to copy to the output dataset. If no layer names are passed, then all source layers are copied.

Performance Hints

When writing into transactional DBMS (SQLite/PostgreSQL,MySQL, etc...), it might be beneficial to increase the number of INSERT statements executed between BEGIN TRANSACTION and COMMIT TRANSACTION statements. This number is specified with the -gt option. For example, for SQLite, explicitly defining -gt 65536 ensures optimal performance while populating some table containing many hundreds of thousands or millions of rows. However, note that -skipfailures overrides -gt and sets the size of transactions to 1.

For PostgreSQL, the *PG_USE_COPY* config option can be set to YES for a significant insertion performance boost. See the PG driver documentation page.

More generally, consult the documentation page of the input and output drivers for performance hints.

Known issues

Starting with GDAL 3.8, ogr2ogr uses internally an Arrow array based API (cf rfc-86) for some source formats (in particular GeoPackage or FlatGeoBuf), and for the most basic types of operations, to improve performance. This substantial change in the ogr2ogr internal logic has required a number of fixes throughout the GDAL 3.8.x bugfix releases to fully stabilize it, and we believe most issues are resolved with GDAL 3.9. If you hit errors not met with earlier GDAL versions, you may specify `--config OGR2OGR_USE_ARROW_API NO` on the ogr2ogr command line to opt for the classic algorithm using an iterative feature based approach. If that flag is needed with GDAL >= 3.9, please file an issue on the GDAL issue tracker.

Return status code

The program returns status code 0 in case of success, and non-zero in case of error (non-blocking errors emitted as warnings are considered as a successful execution).

C API

This utility is also callable from C with *GDALVectorTranslate()*.

Examples

Example 1: Appending to an existing layer

```
ogr2ogr -append -f PostgreSQL PG:dbname=warmerda abc.tab
```

Example 2: Clip input layer with a bounding box

The bounding box is specified as `<xmin> <ymin> <xmax> <ymax>`:

```
ogr2ogr -spat -13.931 34.886 46.23 74.12 output.gpkg natural_earth_vector.gpkg
```

Example 3: Filter Features by a -where clause

```
ogr2ogr -where "\"POP_EST\" < 1000000" \
  output.gpkg natural_earth_vector.gpkg ne_10m_admin_0_countries
```

More examples are given in the individual format pages.

Advanced examples

Example 4: Reprojecting from ETRS_1989_LAEA_52N_10E to EPSG:4326 and clipping to a bounding box

```
ogr2ogr -wrapdateline -t_srs EPSG:4326 -clipdst -5 40 15 55 france_4326.shp␣
↪europe_laea.shp
```

Example 5: Outputting geometries with the CSV driver.

By default this driver does not preserve geometries upon layer creation. An explicit layer creation option is needed:

```
ogr2ogr -lco GEOMETRY=AS_XYZ TrackWaypoint.csv TrackWaypoint.kml
```

Example 6: Extracting only geometries

There are different situations, depending if the input layer has a named geometry column, or not. First check, with **ogrinfo** if there is a reported geometry column.

```
$ ogrinfo -so CadNSDI.gdb.zip PLSSPoint | grep 'Geometry Column'
Geometry Column = SHAPE
```

In that situation where the input format is a FileGeodatabase, it is called SHAPE and can thus be referenced directly in a SELECT statement.

```
ogr2ogr -sql "SELECT SHAPE FROM PLSSPoint" \
  -lco GEOMETRY=AS_XY -f CSV /vsistdout/ CadNSDI.gdb.zip
```

For a shapefile with a unnamed geometry column, `_ogr_geometry_` can be used as a special name to designate the implicit geometry column, when using the default *OGR SQL* dialect. The name begins with an underscore and SQL syntax requires that it must appear between double quotes. In addition the command line interpreter may require that double quotes are escaped and the final SELECT statement could look like:

```
ogr2ogr -sql "SELECT \"_ogr_geometry_\" FROM PLSSPoint" \
  -lco GEOMETRY=AS_XY -f CSV /vsistdout/ CadNSDI.shp
```

If using the *SQL SQLite* dialect, the special geometry name is `geometry` when the source geometry column has no name.

```
ogr2ogr -sql "SELECT geometry FROM PLSSPoint" -dialect SQLite \
  -lco GEOMETRY=AS_XY -f CSV /vsistdout/ CadNSDI.shp
```

5.2.4.4 ogrtindex

Synopsis

```
Usage: ogrtindex [--help] [--long-usage] [--help-general]
                 [-lnum <n>]... [-lname <name>]... [-of <output_format>]
                 [-tileindex <tileindex>] [-write_absolute_path]
                 [-skip_different_projection] [-t_srs <srs_def>]
                 [-src_srs_name <field_name>]
                 [-src_srs_format {AUTO|WKT|EPSG|PROJ}]
                 [-accept_different_schemas]
                 <output_dataset> <src_dataset>...
```

Description

ogrtindex program can be used to create a tileindex - a file containing a list of the identities of a bunch of other files along with their spatial extents. This is primarily intended to be used with MapServer for tiled access to layers using the OGR connection type.

> **Tip**
>
> Equivalent in new "gdal" command line interface:
>
> See *gdal vector index*.

--help

Show this help message and exit

--help-general

Gives a brief usage message for the generic GDAL commandline options and exit.

-lnum <n>

Add layer number `n` from each source file in the tile index.

-lname <name>

Add the layer named `name` from each source file in the tile index.

-f <output_format>

Select an output format name. The default is to create a shapefile.

-tileindex <field_name>

The name to use for the dataset name. Defaults to LOCATION.

-write_absolute_path

Filenames are written with absolute paths

-skip_different_projection

Only layers with same projection ref as layers already inserted in the tileindex will be inserted.

-t_srs <target_srs>

Extent of input files will be transformed to the desired target coordinate reference system. Using this option generates files that are not compatible with MapServer < 7.2. Default creates simple rectangular polygons in the same coordinate reference system as the input vector layers.

-src_srs_name <field_name>

The name of the field to store the SRS of each tile. This field name can be used as the value of the TILESRS keyword in MapServer >= 7.2.

-src_srs_format {AUTO|WKT|EPSG|PROJ}

The format in which the SRS of each tile must be written. Available formats are: AUTO, WKT, EPSG, PROJ.

-accept_different_schemas

By default ogrtindex checks that all layers inserted into the index have the same attribute schemas. If you specify this option, this test will be disabled. Be aware that resulting index may be incompatible with MapServer!

If no *-lnum* or *-lname* arguments are given it is assumed that all layers in source datasets should be added to the tile index as independent records.

If the tile index already exists it will be appended to, otherwise it will be created.

Return status code

The program returns status code 0 in case of success, and non-zero in case of error (non-blocking errors emitted as warnings are considered as a successful execution).

Examples

Example 1

This example would create a shapefile (`tindex.shp`) containing a tile index of the `BL2000_LINK` layers in all the NTF files in the `wrk` directory:

```
ogrtindex tindex.shp wrk/*.NTF
```

5.2.4.5 ogrlineref

Synopsis

```
ogrlineref [--help] [--help-general] [-progress] [-quiet]
           [-f <format_name>] [-dsco <NAME>=<VALUE>]... [-lco <NAME>=<VALUE>]...
           [-create]
           [-l <src_line_datasource_name>] [-ln <layer_name>] [-lf <field_name>]
           [-p <src_repers_datasource_name>] [-pn <layer_name>] [-pm <pos_field_name>] [-
```

(continues on next page)

(continued from previous page)

```
↪pf <field_name>]
          [-r <src_parts_datasource_name>] [-rn <layer_name>]
          [-o <dst_datasource_name>] [-on <layer_name>] [-of <field_name>] [-s <step>]
          [-get_pos] [-x <long>] [-y <lat>]
          [-get_coord] [-m <position>]
          [-get_subline] [-mb <position>] [-me <position>]
```

Description

The **ogrlineref** program can be used to:

- create a linear reference file from input data
- return the "linear referenced" distance for the projection of the input coordinates (point) on the path
- return the coordinates (point) on the path according to the "linear referenced" distance
- return the portion of the path according to the "linear referenced" begin and end distances

The **ogrlineref** utility creates a linear reference - a file containing segments of a certain length (e.g. 1 km in reference units.) The user can get coordinates, linear referenced distances or sublines (subpaths) from this file. The utility does not require the `M` or `Z` components in the geometry. The results can be stored in any OGR supported format. Also some information is written to the stdout.

--help
: Show this help message and exit

--help-general
: Gives a brief usage message for the generic GDAL commandline options and exit.

-progress
: Show progress.

-q, --quiet
: Suppress progress messages and other non-error output.

-f `<format_name>`
: Select an output format name. The default is to create a shapefile.

-dsco `<NAME>=<VALUE>`
: Dataset creation option (format specific)

-lco `<NAME>=<VALUE>`
: Layer creation option (format specific).

-create
: Create the linear reference file (linestring of parts).

-l `<src_line_datasource_name>`
: The path to input linestring datasource (e.g. the road)

-ln `<layer_name>`
: The layer name in datasource

-lf `<field_name>`
: The field name of unique values to separate the input lines (e.g. the set of roads).

-p <src_repers_datasource_name>
The path to linear references points (e.g. the road mile-stones)

-pn <layer_name>
The layer name in datasource

-pm <pos_field_name>
The field name of distances along path (e.g. mile-stones values)

-pf <field_name>
The field name of unique values to map input reference points to lines.

-r <src_parts_datasource_name>
The path to linear reference file.

-rn <layer_name>
The layer name in datasource

-o <dst_datasource_name>
The path to output linear reference file (linestring datasource)

-on <layer_name>
The layer name in datasource

-of <field_name>
The field name for storing the unique values of input lines

-s <step>
The part size in linear units

-get_pos
Return linear referenced position for input X, Y

-x <long>
Input X coordinate

-y <lat>
Input Y coordinate

-get_coord
Return point on path for input linear distance

-m <position>
The input linear distance

-get_subline
Return the portion of the input path from and to input linear positions.

-mb <position>
The input begin linear distance

-me <position>
The input end linear distance

Return status code

The program returns status code 0 in case of success, and non-zero in case of error (non-blocking errors emitted as warnings are considered as a successful execution).

Examples

Example 1

This example would create a shapefile (`parts.shp`) containing a data needed for linear referencing (1 km parts):

```
ogrlineref -create -l roads.shp -p references.shp -pm dist -o parts.shp -s 1000 -progress
```

5.2.4.6 ogrmerge

Synopsis

```
ogrmerge [--help] [--help-general]
            -o <out_dsname> <src_dsname> [<src_dsname>]...
            [-f format] [-single] [-nln <layer_name_template>]
            [-update | -overwrite_ds] [-append | -overwrite_layer]
            [-src_geom_type <geom_type_name>[,<geom_type_name>]...]
            [-dsco <NAME>=<VALUE>]... [-lco <NAME>=<VALUE>]...
            [-s_srs <srs_def>] [-t_srs <srs_def> | -a_srs <srs_def>]
            [-progress] [-skipfailures] [--help-general]
```

Options specific to the *-single* option:

```
[-field_strategy FirstLayer|Union|Intersection]
[-src_layer_field_name <name>]
[-src_layer_field_content <layer_name_template>]
```

Description

ogrmerge takes as input several vector datasets, each of them having one or several vector layers, and copies them into a target dataset.

There are essentially two modes:

- the default one, where each input vector layer, is copied as a separate layer into the target dataset
- another one, activated with the -single switch, where the content of all input vector layers is appended into a single target layer. This assumes that the schema of those vector layers is more or less the same.

Internally this generates a *VRT -- OGR Virtual Format* file, and if the output format is not VRT, final translation is done with **ogr2ogr** or `gdal.VectorTranslate()`. So, for advanced uses, output to VRT, potential manual editing of it and **ogr2ogr** can be done.

> **Note**
>
> ogrmerge is a Python utility, and is only available if GDAL Python bindings are available.

> **Tip**
>
> Equivalent in new "gdal" command line interface:
>
> See *gdal vector concat*.

--help

Show this help message and exit

--help-general

Gives a brief usage message for the generic GDAL commandline options and exit.

-o <out_dsname>

Output dataset name. Required.

<src_dsname>

One or several input vector datasets. Required

-f <format>

Select the output format. If not specified, the format is guessed from the extension (previously was ESRI Shapefile). Use the short format name

-single

If specified, all input vector layers will be merged into a single one.

-nln <layer_name_template>

Name of the output vector layer (in single mode, and the default is "merged"), or template to name the output vector layers in default mode (the default value is {AUTO_NAME}). The template can be a string with the following variables that will be substituted with a value computed from the input layer being processed:

- {AUTO_NAME}: equivalent to {DS_BASENAME}_{LAYER_NAME} if both values are different, or {LAYER_NAME} when they are identical (case of shapefile).
- {DS_NAME}: name of the source dataset
- {DS_BASENAME}: base name of the source dataset
- {DS_INDEX}: index of the source dataset
- {LAYER_NAME}: name of the source layer
- {LAYER_INDEX}: index of the source layer

-update

Open an existing dataset in update mode.

-overwrite_ds

Overwrite the existing dataset if it already exists (for file based datasets)

-append

Open an existing dataset in update mode, and if output layers already exist, append the content of input layers to them.

-overwrite_layer

Open an existing dataset in update mode, and if output layers already exist, replace their content with the one of the input layer.

-src_geom_type <geom_type_name>[,<geom_type_name>]...

Only take into account input layers whose geometry type match the type(s) specified. Valid values for geom_type_name are GEOMETRY, POINT, LINESTRING, POLYGON, MULTIPOINT, MULTILINESTRING, MULTIPOLYGON, GEOMETRYCOLLECTION, CIRCULARSTRING, CURVEPOLYGON, MULTICURVE, MULTISURFACE, CURVE, SURFACE, TRIANGLE, POLYHEDRALSURFACE and TIN.

-dsco <NAME>=<VALUE>

Dataset creation option (format specific)

-lco <NAME>=<VALUE>

Layer creation option (format specific)

-a_srs <srs_def>

Assign an output SRS

-t_srs <srs_def>

Reproject/transform to this SRS on output

-s_srs <srs_def>

Override source SRS

-progress

Display progress on terminal. Only works if input layers have the "fast feature count" capability.

-skipfailures

Continue after a failure, skipping the failed feature.

-field_strategy `FirstLayer|Union|Intersection`

Only used with *-single*. Determines how the schema of the target layer is built from the schemas of the input layers. May be FirstLayer to use the fields from the first layer found, Union to use a super-set of all the fields from all source layers, or Intersection to use a sub-set of all the common fields from all source layers. Defaults to Union.

-src_layer_field_name <name>

Only used with *-single*. If specified, the schema of the target layer will be extended with a new field 'name', whose content is determined by -src_layer_field_content. See *Example 3*.

-src_layer_field_content <layer_name_template>

Only used with *-single*. If specified, the schema of the target layer will be extended with a new field (whose name is given by *-src_layer_field_name*, or 'source_ds_lyr' otherwise), whose content is determined by `layer_name_template`. The syntax of `layer_name_template` is the same as for *-nln*.

Return status code

The program returns status code 0 in case of success, and non-zero in case of error (non-blocking errors emitted as warnings are considered as a successful execution).

Examples

Example 1: Creating a VRT with a layer for each input shapefile

```
ogrmerge -o merged.vrt *.shp
```

Example 2: Creating a GeoPackage with a layer for each input shapefile

```
ogrmerge -o merged.gpkg *.shp
```

Example 3: Adding a field to indicate the source layer

Concatenate the content of `france.shp` and `germany.shp` in `merged.shp`, and add a 'country' field to each feature whose value is 'france' or 'germany' depending where it comes from:

```
ogrmerge -single -o merged.shp france.shp germany.shp -src_layer_field_name country
```

5.2.4.7 ogr_layer_algebra

Added in version 3.6.

Synopsis

```
ogr_layer_algebra [--help] [--help-general]
                    Union|Intersection|SymDifference|Identity|Update|Clip|Erase
                    -input_ds <path> [-input_lyr <name>]
                    -method_ds <path> [-method_lyr <name>]
                    -output_ds <path> [-output_lyr <name>] [-overwrite]
                    [-opt <NAME>=<VALUE>]...
                    [-f <format_name>] [-dsco <NAME>=<VALUE>]... [-lco <NAME>=<VALUE>]...
                    [-input_fields {NONE|ALL|<fld1>,<fl2>,...<fldN>}] [-method_fields
↪{NONE|ALL|<fld1>,<fl2>,...<fldN>}]
                    [-nlt <geom_type>] [-a_srs <srs_def>]
```

Description

The **ogr_layer_algebra** provides a command line utility to perform various vector layer algebraic operations. The utility takes a vector input source and a method source and generates the output of the operation in the specified output file.

> **Note**
>
> ogr_layer_algebra is a Python utility, and is only available if GDAL Python bindings are available.

> **Tip**
>
> Equivalent in new "gdal" command line interface:
>
> See *gdal vector layer-algebra*.

--help

Show this help message and exit

--help-general

Gives a brief usage message for the generic GDAL commandline options and exit.

<mode>

Where <mode> is one of the seven available modes:

- `Union`

  A union is a set of features, which represent areas that are in either of the operand layers.

- `Intersection`

  An intersection is a set of features, which represent the common areas of two layers.

- `SymDifference`

A symmetric difference is a set of features, which represent areas that are in operand layers but which do not intersect.

- `Identity`

  The identity method identifies features in the input layer with features in the method layer possibly splitting features into several features. By default the result layer has attributes from both operand layers.

- `Update`

  The update method creates a layer, which add features into the input layer from the method layer possibly cutting features in the input layer. By default the result layer has attributes only from the input layer.

- `Clip`

  The clip method creates a layer, which has features from the input layer clipped to the areas of the features in the method layer. By default the result layer has attributes of the input layer.

- `Erase`

  The erase method creates a layer, which has features from the input layer whose areas are erased by the features in the method layer. By default the result layer has attributes of the input layer.

-input_ds <path>

Input dataset path for the operation to be performed. For operations involving two datasets, this is one of the datasets.

-input_lyr <name>

Layer name of the `input_ds` for which the operations have to be performed (Optional)

-method_ds <path>

Method data set path for the operation to be performed. This is usually the conditional data set supplied to the operation (ex: clip , erase , update) This is the Second data set in the operation (ex : Union, Intersection , SymDifference)

-method_lyr <name>

Layer name of the `method_ds` for which the operations have to be performed (Optional)

-output_ds <path>

Output data set path for writing the result of the operations performed by `ogr_layer_algebra`.

-output_lyr_name <name>

Layer name of the `output_lyr_name` where the output vector has to be written. (Optional)

-overwrite

Indicates whether the `output_ds` have to be overwritten with the generated result of `ogr_layer_algebra`.

-opt <NAME>=<VALUE>

Attributes for which the operation has to run on `input_ds` and `method_ds`.

-f <format_name>

Select the output format.If not specified, the format is guessed from the extension (previously was ESRI Shapefile). Use the short format name

-dsco <NAME>=<VALUE>

Dataset creation option (format specific).

-lco <NAME>=<VALUE>

Layer creation option (format specific).

-input_fields {NONE|ALL|<fld1>,<fl2>,...<fldN>}

Comma-delimited list of fields from input layer to copy to the output layer , if eligible according to the operation.

-method_fields {NONE|ALL|<fld1>,<fl2>,...<fldN>}

Comma-delimited list of fields from method layer to copy to the output layer , if eligible according to the operation.

-nlt <geom_type>

Define the geometry type for the created layer. One of NONE, GEOMETRY, POINT, LINESTRING, POLYGON, GEOMETRYCOLLECTION, MULTIPOINT, MULTIPOLYGON, GEOMETRY25D, POINT25D, LINESTRING25D, POLYGON25D, GEOMETRYCOLLECTION25D, MULTIPOINT25D, MULTIPOLYGON25D.

-a_srs <srs_def>

Assign an output SRS, but without reprojecting

The coordinate reference systems that can be passed are anything supported by the OGRSpatialReference.SetFromUserInput() call, which includes EPSG Projected, Geographic or Compound CRS (i.e. EPSG:4296), a well known text (WKT) CRS definition, PROJ.4 declarations, or the name of a .prj file containing a WKT CRS definition.

Return status code

The program returns status code 0 in case of success, and non-zero in case of error (non-blocking errors emitted as warnings are considered as a successful execution).

5.2.5 Geographic network programs

5.2.5.1 gnmmanage

Synopsis

```
Usage: gnmmanage [--help][--help-general][-q][-quiet][--long-usage]
                 [info]
                 [create [-f <format_name>] [-t_srs <srs_name>] [-dsco <NAME>=<VALUE>]...
↪ ]
                 [import <src_dataset_name>] [-l <layer_name>]
                 [connect <gfid_src> <gfid_tgt> <gfid_con> [-c <cost>] [-ic <inv_cost>]␣
↪[-dir <dir>]]
                 [disconnect <gfid_src> <gfid_tgt> <gfid_con>]
                 [rule <rule_str>]
                 [autoconnect <tolerance>]
                 [delete]
                 [change [-bl <gfid>][-unbl <gfid>][-unblall]]
                 <gnm_name> [<layer> [<layer>]...]
```

Description

The **gnmmanage** program can perform various managing operations on geographical networks in GDAL. In addition to creating and deleting networks this includes capabilities of managing network's features, topology and rules.

--help

Show this help message and exit

--help-general

Gives a brief usage message for the generic GDAL commandline options and exit.

-info

Different information about network: system and class layers, network metadata, network spatial reference.

create

Create network.

-f <format_name>

Output file format name.

-t_srs <srs_name>

Spatial reference input.

-dsco <NAME>=<VALUE>

Network creation option set as pair name=value.

import <src_dataset_name>

Import layer with dataset name to copy.

-l <layer_name>

Layer name in dataset. If unset, 0 layer is copied.

connect <gfid_src> <gfid_tgt> <gfid_con>

Make a topological connection, where the gfid_src and gfid_tgt are vertices and gfid_con is edge (gfid_con can be -1, so the system edge will be inserted).

Manually assign the following values:

-c <cost>

Cost / weight

-ic <invcost>

Inverse cost

-dir <dir>

Direction of the edge.

disconnect <gfid_src> <gfid_tgt> <gfid_con>

Removes the connection from the graph.

rule <rule_str>

Creates a rule in the network by the given rule_str string.

autoconnect <tolerance>

Create topology automatically with the given double tolerance and layer names. In no layer name provided all layers of network will be used.

delete

Delete network.

change

Change blocking state of network edges or vertices.

-bl <gfid>

Block feature before the main operation. Blocking features are saved in the special layer.

-unbl <gfid>

Unblock feature before the main operation.

-unblall

Unblock all blocked features before the main operation.

<gnm_name>

The network to work with (path and name).

<layer>

The network layer name.

Return status code

The program returns status code 0 in case of success, and non-zero in case of error (non-blocking errors emitted as warnings are considered as a successful execution).

5.2.5.2 gnmanalyse

Synopsis

```
Usage: gnmanalyse [--help][--help-general][-q][-quiet][--long-usage]
                  [dijkstra <start_gfid> <end_gfid [-alo <NAME>=<VALUE>]...]
                  [kpaths <start_gfid> <end_gfid> <k> [-alo NAME=VALUE]...]
                  [resource [-alo <NAME>=<VALUE>]...]
                  [-ds <ds_name>][-f <ds_format>][-l <layer_name>]
                  [-dsco <NAME>=<VALUE>]... [-lco <NAME>=<VALUE>]...
                  <gnm_name>
```

Description

The **gnmanalyse** program provides analysing capabilities of geographical networks in GDAL. The results of calculations are return in an OGRLayer format or as a console text output if such layer is undefined. All calculations are made considering the blocking state of features.

--help

Show this help message and exit

--help-general

Gives a brief usage message for the generic GDAL commandline options and exit.

dijkstra <start_gfid> <end_gfid>

Calculates the best path between two points using Dijkstra algorithm from start_gfid point to end_gfid point.

kpaths <start_gfid> <end_gfid>

Calculates K shortest paths between two points using Yen's algorithm (which internally uses Dijkstra algorithm for single path calculating) from start_gfid point to end_gfid point.

resource

Calculates the "resource distribution". The connected components search is performed using breadth-first search and starting from that features which are marked by rules as 'EMITTERS'.

-d <ds_name>

The name and path of the dataset to save the layer with resulting paths. Not need to be existed dataset.

-f <ds_format>

Define this to set the format of newly created dataset.

-l <layer_name>

The name of the resulting layer. If the layer exist already - it will be rewritten.

<gnm_name>

The network to work with (path and name).

-dsco <NAME>=<VALUE>

Dataset creation option (format specific)

-lco <NAME>=<VALUE>

Layer creation option (format specific)

-alo <NAME>=<VALUE>

Algorithm option (format specific)

Return status code

The program returns status code 0 in case of success, and non-zero in case of error (non-blocking errors emitted as warnings are considered as a successful execution).

5.2.6 Other utilities

5.2.6.1 sozip

Added in version 3.7.

Synopsis

```
sozip [--help] [--help-general]
      [--quiet|--verbose]
      [[-g|--grow] | [--overwrite]]
      [-r|--recurse-paths]
      [-j|--junk-paths]
      [-l|--list]
      [--optimize-from=<input.zip>]
      [--validate]
      [--enable-sozip={auto|yes|no}]
      [--sozip-chunk-size=<value>]
      [--sozip-min-file-size=<value>]
      [--content-type=<value>]
      <zip_filename> [<filename>]...
```

Description

The **sozip** utility can be used to:

- create a *SOZip (Seek-Optimized ZIP)* file
- append files to an existing ZIP/SOZip file
- list the contents of a ZIP/SOZip file

- validate a SOZip file
- convert an existing Zip file in a SOZip optimized one

Tip

Equivalent in new "gdal" command line interface:

See *gdal vsi sozip*.

--help

Show this help message and exit

--help-general

Gives a brief usage message for the generic GDAL commandline options and exit.

--quiet

Quiet mode. No progress message is emitted on the standard output.

--verbose

Verbose mode.

-g

--grow

Grow an existing zip file with the content of the specified filename(s). This is the default mode of the utility. This switch is here for compatibility with Info-ZIP **zip** utility

--overwrite

Overwrite the target zip file if it already exists.

-l

--list

List the files contained in the zip file in an output similar to Info-ZIP **unzip** utility, but with the addition of a column indicating whether each file is seek-optimized.

--validate

Validates a SOZip file. Baseline ZIP validation is done in a light way, limited to being able to browse through ZIP records with the InfoZIP-based ZIP reader used by GDAL. But validation of the SOZip-specific aspects is done more thoroughly.

-r

--recurse-paths

Travels the directory structure of the specified directory/directories recursively.

-j

--junk-paths

Store just the name of a saved file (junk the path), and do not store directory names. By default, sozip will store the full path (relative to the current directory).

--optimize-from=<input.zip>

Re-process {input.zip} to generate a SOZip-optimized .zip. Options *--enable-sozip*, *--sozip-chunk-size* and *--sozip-min-file-size* may be used in that mode.

--enable-sozip={auto|yes|no}

In auto mode, a file is seek-optimized only if its size is above the value of *--sozip-min-file-size*. In yes mode, all input files will be seek-optimized. In no mode, no input files will be seek-optimized.

--sozip-chunk-size=<value>

Chunk size for a seek-optimized file. Defaults to 32768 bytes. The value is specified in bytes, or K and M suffix can be respectively used to specify a value in kilo-bytes or mega-bytes.

--sozip-min-file-size=<value>

Minimum file size to decide if a file should be seek-optimized, in --enable-sozip=auto mode. Defaults to 1 MB byte. The value is specified in bytes, or K, M or G suffix can be respectively used to specify a value in kilo-bytes, mega-bytes or giga-bytes.

--content-type=<value>

Store the Content-Type for the file being added as a key-value pair in the extra field extension 'KV' (0x564b) dedicated to storing key-value pair metadata

<zip_filename>

Filename of the zip file to create/append to/list.

<filename>

Filename of the file to add.

Multithreading

The *GDAL_NUM_THREADS* configuration option can be set to ALL_CPUS or a integer value to specify the number of threads to use for SOZip-compressed files. Defaults to ALL_CPUS.

Return status code

The program returns status code 0 in case of success, and non-zero in case of error (non-blocking errors emitted as warnings are considered as a successful execution).

C API

Functionality of this utility can be done from C with *CPLAddFileInZip()* or *VSICopyFile()*.

Examples

Create a, potentially seek-optimized, ZIP file with the content of my.gpkg:

```
sozip my.gpkg.zip my.gpkg
```

Create a, potentially seek-optimized, ZIP file from the content of a source directory:

```
sozip -r my.gpkg.zip source_dir/
```

Create a, potentially seek-optimized, ZIP file from an existing ZIP file.

```
sozip --convert-from=in.zip out.zip
```

List the contents of a ZIP file and display which files are seek-optimized:

```
sozip -l my.gpkg.zip
```

Validates a SOZip file:

```
sozip --validate my.gpkg.zip
```

- (1): Creation refers to implementing `GDALCreate()`.
- (2): Copy refers to implementing `GDALCreateCopy()`.

Note

The following drivers have been removed in GDAL 3.5: BPG, E00GRID, EPSILON, IGNFHeightASCIIGrid, NTv1

The following drivers have been removed in GDAL 3.11: BLX, CTable2, ELAS, FIT, JP2Lura, OZI, Rasterlite (v1), R object data store (.rda), RDB, SDTS, SGI, XPM

Write support for the following formats has been removed in GDAL 3.11: ADRG, BYN, LAN, MFF, MFF2/HKV, ISIS2, PAux, USGSDEM

6.1 AAIGrid -- Arc/Info ASCII Grid

Driver short name

AAIGrid

Driver built-in by default

This driver is built-in by default

Supported for read and write access, including reading of an affine georeferencing transform and some projections. This format is the ASCII interchange format for Arc/Info Grid, and takes the form of an ASCII file, plus sometimes an associated .prj file. It is normally produced with the Arc/Info ASCIIGRID command.

The projections support (read if a *.prj file is available) is quite limited. Additional sample .prj files may be sent to the maintainer, warmerdam@pobox.com.

The NODATA value for the grid read is also preserved when available in the same format as the band data.

The following configuration options are supported:

- **AAIGRID_DATATYPE=[Int32/Float32/Float64]:** By default, the datatype returned for AAIGRID datasets by GDAL is autodetected, and set to Float32 for grid with floating point values or Int32 otherwise. This is done by analysing the format of the NODATA value and, if needed, the data of the grid. You can explicitly specify the datatype by setting the AAIGRID_DATATYPE configuration option.
- **FORCE_CELLSIZE=[YES/NO]:** If pixels being written are not square (the width and height of a pixel in georeferenced units differ) then DX and DY parameters will be output instead of CELLSIZE. Such files can be used in Golden Surfer, but not most other ascii grid reading programs. For force the X pixel size to be used as CELLSIZE use the FORCE_CELLSIZE=YES creation option or resample the input to have square pixels.
- **DECIMAL_PRECISION=<integer>:** When writing floating-point values, the driver uses the "%.20g" format pattern as a default. You can consult a reference manual for printf to have an idea of the exact behavior of this ;-). You can alternatively specify the number of decimal places with the DECIMAL_PRECISION creation option. For example, DECIMAL_PRECISION=3 will output numbers with 3 decimal places(using %lf format). Another option is SIGNIFICANT_DIGITS=3, which will output 3 significant digits (using %g format).

The *AIG -- Arc/Info Binary Grid* driver is also available for Arc/Info Binary Grid format.

NOTE: Implemented as aaigriddataset.cpp.

6.1.1 Driver capabilities

Supports CreateCopy()

This driver supports the `GDALDriver::CreateCopy()` operation

Supports Georeferencing

This driver supports georeferencing

Supports VirtualIO

This driver supports *virtual I/O operations (/vsimem/, etc.)*

6.2 ACE2 -- ACE2

Driver short name

ACE2

Driver built-in by default

This driver is built-in by default

This is a convenience driver to read ACE2 DEMs. Those files contain raw binary data. The georeferencing is entirely determined by the filename. Quality, source and confidence layers are of Int16 type, whereas elevation data is returned as Float32.

ACE2 product overview

NOTE: Implemented as ace2dataset.cpp.

6.2.1 Driver capabilities

Supports Georeferencing

This driver supports georeferencing

Supports VirtualIO

This driver supports *virtual I/O operations (/vsimem/, etc.)*

6.3 ADRG -- ADRG/ARC Digitized Raster Graphics (.gen/.thf)

Driver short name

ADRG

Driver built-in by default

This driver is built-in by default

Supported by GDAL for read access.

An ADRG dataset is made of several files. The file recognised by GDAL is the General Information File (.GEN). GDAL will also need the image file (.IMG), where the actual data is.

The Transmission Header File (.THF) can also be used as an input to GDAL. If the THF references more than one image, GDAL will report the images it is composed of as subdatasets. If the THF references just one image, GDAL will open it directly.

Overviews, legends and insets are not used. Polar zones (ARC zone 9 and 18) are not supported (due to the lack of test data).

See also : the ADRG specification (MIL-A-89007)

6.3.1 Driver capabilities

Supports Georeferencing

This driver supports georeferencing

Supports VirtualIO

This driver supports *virtual I/O operations (/vsimem/, etc.)*

6.4 AIG -- Arc/Info Binary Grid

Driver short name

AIG

Driver built-in by default

This driver is built-in by default

Supported by GDAL for read access. This format is the internal binary format for Arc/Info Grid, and takes the form of a coverage level directory in an Arc/Info database. To open the coverage select the coverage directory, or an .adf file (such as hdr.adf) from within it. If the directory does not contain file(s) with names like w001001.adf then it is not a grid coverage.

Support includes reading of an affine georeferencing transform, some projections, and a color table (.clr) if available.

This driver is implemented based on a reverse engineering of the format. See the *Arc/Info Binary Grid Format* for more details.

The projections support (read if a prj.adf file is available) is quite limited. Additional sample prj.adf files may be sent to the maintainer, warmerdam@pobox.com.

NOTE: Implemented as aigdataset.cpp.

6.4.1 Driver capabilities

Supports Georeferencing

This driver supports georeferencing

Supports VirtualIO

This driver supports *virtual I/O operations (/vsimem/, etc.)*

6.4.1.1 Arc/Info Binary Grid Format

by Frank Warmerdam (warmerdam@pobox.com)

The Arc/Info Binary Grid format is the internal working format of the Arc/Info Grid product. It is also usable and creatable within the spatial analyst component of ArcView. It is a tiled (blocked) format with run length compression capable of holding raster data of up to 4 byte integers or 4 byte floating data.

This format should not be confused with the Arc/Info ASCII Grid format which is the interchange format for grids. Files can be converted between binary and ASCII format with the GRIDASCII and ASCIIGRID commands in Arc/Info. This format is also different than the flat binary raster output of the GRIDFLOAT command. The Arc/Info binary float, and ASCII formats are also accessible from within ArcView.

This format should also not be confused with what I know as ESRI BIL format. This is really a standard ESRI way of creating a header file (.HDR) describing the data layout a binary raster file containing raster data.

Version

I am not sure yet how the versions work for grid files. I have been working primarily with grid files generated by ArcView 3.x, and its associated gridio API. The hdr.adf files I have examined start with the string **GRID1.2** for what that's worth. Certainly the file naming conventions seem to follow the Arc/Info 7.x conventions rather than that of earlier versions.

File Set

A grid coverage actually consists of a number of files. A grid normally lives in its own directory named after the grid. For instance, the grid **nwgrd1** lives in the directory **nwgrd1**, and has the following component files:

```
-rwxr--r--   1 warmerda users          32 Jan 22 16:07 nwgrd1/dblbnd.adf
-rwxr--r--   1 warmerda users         308 Jan 22 16:07 nwgrd1/hdr.adf
-rwxr--r--   1 warmerda users          32 Jan 22 16:07 nwgrd1/sta.adf
-rwxr--r--   1 warmerda users        2048 Jan 22 16:07 nwgrd1/vat.adf
-rwxr--r--   1 warmerda users      187228 Jan 22 16:07 nwgrd1/w001001.adf
-rwxr--r--   1 warmerda users        6132 Jan 22 16:07 nwgrd1/w001001x.adf
```

Sometimes datasets will also include a prj.adf files containing the projection definition in the usual ESRI format. Grids also normally have associated tables in the info directory. This is beyond the scope of my discussion for now.

The files have the following roles:

- *dblbnd.adf*: Contains the bounds (LLX, LLY, URX, URY) of the portion of utilized portion of the grid.
- *hdr.adf*: This is the header, and contains information on the tile sizes, and number of tiles in the dataset. It also contains assorted other information I have yet to identify.
- *sta.adf*: This contains raster statistics. In particular, the raster min, max, mean and standard deviation.
- **vat.adf**: This relates to the value attribute table. This is the table corresponding integer raster values with a set of attributes. I presume it is really just a pointer into info in a manner similar to the pat.adf file in a vector coverage, but I haven't investigated yet.
- *w001001.adf*: This is the file containing the actual raster data.
- *w001001x.adf*: This is an index file containing pointers to each of the tiles in the w001001.adf raster file.

---

dblbnd.adf - Georef Bounds

Fields:

Start Byte

# of Bytes

Format

Name

Description

0

8

MSB double

D_LLX

Lower left X (easting) of the grid. Generally -0.5 for an ungeoreferenced grid.

8

8

MSB double

D_LLY

Lower left Y (northing) of the grid. Generally -0.5 for an ungeoreferenced grid.

16

8

MSB double

D_URX

Upper right X (easting) of the grid. Generally #Pixels-0.5 for an ungeoreferenced grid.

24

8

MSB double

D_URY

Upper right Y (northing) of the grid. Generally #Lines-0.5 for an ungeoreferenced grid.

This file is always 32 bytes long. The bounds apply to the portion of the grid that is in use, not the whole thing.

---

w001001x.adf - Tile Index

This is a binary dump of the first 320 bytes of a w001001x.adf file.

8

16

zero fill

24

4

MSB Int32

RFileSize

Size of whole file in shorts (multiply by two to get file size in bytes).

28

72

zero fill

100, ...

2

MSB Int16

RTileSize

Size of this tiles data measured in shorts. This matches the size in the index file, and does not include the tile size itself. The next tile starts **2*n+2** bytes after the start of this tile, where **n** is the value of this field.

102, ...

1

byte

RTileType

Tile type code indicating the organization of the following data (integer coverages only).

103, ...

1

byte

RMinSize

Number of bytes following to form the minimum value for the tile (integer coverages only).

104, ...

(RMinSize bytes)

MSB Int (var size)

RMin

The minimum value pixels for this tile. This number is added to the pixel values for each pixel in this tile (integer coverages only). I must stress that if RMinSize is less than 4 this is still a signed quantity. For instance, if RMinSize is 2, the value is 65536 - byte0*256 - byte1 if byte0 is > 127.

104+RMinSize, ...

RTileSize*2 - 3 - RMinSize

variable

RTileData

The data for this tile. Format varies according to RTileType for integer coverages.

The fields RTileSize, RTileType, RMinSize, RMin, and RTileData occur in the file for each tile of data present. They are usually packed one after the other, but this isn't necessarily guaranteed. The index file (w001001x.adf) should be used to establish the tile locations. Note that tiles that appear in the index file with a size of zero will appear as just two bytes (zeros) for the RTileSize for that tile.

Raster Size

The size of a the grid isn't as easy to deduce as one might expect. The hdr.adf file contains the HTilesPerRow, HTilesPerColumn, HTileXSize, and HTileYSize fields which imply a particular raster space. However, it seems that this is created much larger than necessary to hold the users raster data. I have created 3x1 rasters which resulted in the standard 8x512 tiles of 256x4 pixels each.

It seems that the user portion of the raster has to be computed based on the georeferenced bounds in the dblbnd.adf file (assumed to be anchored at the top left of the total raster space), and the HPixelSizeX, and HPixelSizeY fields from hdr.adf.

#Pixels = (D_URX - D_LRX) / HPixelSizeX

#Lines = (D_URY - D_LRY) / HPixelSizeY

Based on this number of pixels and lines, it is possible to establish what portion out of the top left of the raster is really *of interest*. All regions outside this appear to empty tiles, or filled with no data markers.

RTileType/RTileData

Each tile contains HBlockXSize * HBlockYSize pixels of data. For floating point and uncompressed integer files the data is just the tile size (in two bytes) followed by the pixel data as 4 byte MSB order IEEE floating point words. For compressed integer tiles it is necessary to interpret the RTileType to establish the details of the tile organization:

RTileType = 0x00 (constant block)

All pixels take the value of the RMin. Data is ignored. It appears there is sometimes a bit of meaningless data (up to four bytes) in the block.

RTileType = 0x01 (raw 1bit data)

One full tile worth of data pixel values follows the RMin field, with 1bit per pixel.

RTileType = 0x04 (raw 4bit data)

One full tiles worth of data pixel values follows the RMin field, with 4 bits per pixel. The high order four bits of a byte comes before the low order four bits.

RTileType = 0x08 (raw byte data)

One full tiles worth of data pixel values (one byte per pixel) follows the RMin field.

RTileType = 0x10 (raw 16bit data)

One full tiles worth of data pixel values follows the RMin field, with 16 bits per pixel (MSB).

RTileType = 0x20 (raw 32bit data)

One full tiles worth of data pixel values follows the RMin field, with 32 bits per pixel (MSB).

RTileType = 0xCF (16 bit literal runs/nodata runs)

The data is organized in a series of runs. Each run starts with a marker which should be interpreted as:

- **Marker < 128**: The marker is followed by **Marker** pixels of literal data with two MSB bytes per pixel.
- **Marker > 127**: The marker indicates that **256-Marker** pixels of *no data* pixels should be put into the output stream. No data (other than the next marker) follows this marker.

RTileType = 0xD7 (literal runs/nodata runs)

The data is organized in a series of runs. Each run starts with a marker which should be interpreted as:

- **Marker < 128**: The marker is followed by **Marker** pixels of literal data with one byte per pixel.
- **Marker > 127**: The marker indicates that **256-Marker** pixels of *no data* pixels should be put into the output stream. No data (other than the next marker) follows this marker.

RTileType = 0xDF (RMin runs/nodata runs)

The data is organized in a series of runs. Each run starts with a marker which should be interpreted as:

- **Marker < 128**: The marker is followed by **Marker** pixels of literal data with one byte per pixel.
- **Marker > 127**: The marker indicates that **256-Marker** pixels of *no data* pixels should be put into the output stream. No data (other than the next marker) follows this marker.

This is similar to 0xD7, except that the data size is zero bytes instead of 1, so only RMin values are inserted into the output stream.

RTileType = 0xE0 (run length encoded 32bit)

The data is organized in a series of runs. Each run starts with a marker which should be interpreted as a **count**. The four bytes following the count should be interpreted as an MSB Int32 **value**. They indicate that **count** pixels of **value** should be inserted into the output stream.

RTileType = 0xF0 (run length encoded 16bit)

The data is organized in a series of runs. Each run starts with a marker which should be interpreted as a **count**. The two bytes following the count should be interpreted as an MSB Int16 **value**. They indicate that **count** pixels of **value** should be inserted into the output stream.

RTileType = 0xFC/0xF8 (run length encoded 8bit)

The data is organized in a series of runs. Each run starts with a marker which should be interpreted as a **count**. The following byte is the **value**. They indicate that **count** pixels of **value** should be inserted into the output stream.

The interpretation is the same for 0xFC, and 0xF8. I believe that 0xFC has a lower dynamic (2 bit) range than 0xF8 (4 or 8 bit).

RTileType = 0xFF (RMin CCITT RLE 1Bit)

The data stream for this file is CCITT RLE (G1 fax) compressed. The format is complex but source is provided with the sample program (derived from libtiff) for reading it. The result of uncompressing is 1bit data so which the RMin value should be added.

---

hdr.adf - Header

This is a binary dump of the first 308 bytes of a hdr.adf file.

Acknowledgements

I would like to thank Geosoft Inc. for partial funding of my research into this format. I would also like to thank:

- Kenneth R. McVay for providing the statistics file format.
- Noureddine Farah of ThinkSpace who dug up lots of datasets that caused problems.
- Luciano Fonseca who worked out RTileType 0x01.
- Martin Manningham of Global Geomatics for additional problem sample files.
- Harry Anderson of EDX Engineering, for showing me that floating point tiles don't have RTileType.
- Ian Turton for supplying a sample files demonstrating the need to be careful with the sign of "short" RMin values.
- Duncan Chaundy at PCI for poking hard till I finally deduced 0xFF tiles.
- Stephen Cheeseman of GeoSoft for yet more problem files.
- Geoffrey Williams for a files demonstrating tile type 0x20.

6.5 AIRSAR -- AIRSAR Polarimetric Format

Driver short name

AIRSAR

Driver built-in by default

This driver is built-in by default

Most variants of the AIRSAR Polarimetric Format produced by the AIRSAR Integrated Processor are supported for reading by GDAL. AIRSAR products normally include various associated data files, but only the imagery data themselves is supported. Normally these are named *mission*_l.dat (L-Band) or *mission*_c.dat (C-Band).

AIRSAR format contains a polarimetric image in compressed stokes matrix form. Internally GDAL decompresses the data into a stokes matrix, and then converts that form into a covariance matrix. The returned six bands are the six values needed to define the 3x3 Hermitian covariance matrix. The convention used to represent the covariance matrix in terms of the scattering matrix elements HH, HV (=VH), and VV is indicated below. Note that the non-diagonal elements of the matrix are complex values, while the diagonal values are real (though represented as complex bands).

- Band 1: Covariance_11 (Float32) = HH*conj(HH)

- Band 2: Covariance_12 (CFloat32) = sqrt(2)*HH*conj(HV)
- Band 3: Covariance_13 (CFloat32) = HH*conj(VV)
- Band 4: Covariance_22 (Float32) = 2*HV*conj(HV)
- Band 5: Covariance_23 (CFloat32) = sqrt(2)*HV*conj(VV)
- Band 6: Covariance_33 (Float32) = VV*conj(VV)

The identities of the bands are also reflected in metadata and in the band descriptions.

The AIRSAR product format includes (potentially) several headers of information. This information is captured and represented as metadata on the file as a whole. Information items from the main header are prefixed with "MH_", items from the parameter header are prefixed with "PH_" and information from the calibration header are prefixed with "CH_". The metadata item names are derived automatically from the names of the fields within the header itself.

No effort is made to read files associated with the AIRSAR product such as *mission*_l.mocomp, *mission*_meta.airsar or *mission*_meta.podaac.

6.5.1 Driver capabilities

Supports VirtualIO

This driver supports *virtual I/O operations (/vsimem/, etc.)*

6.5.2 See Also

- AIRSAR Data Format

6.6 AVIF -- AV1 Image File Format

Added in version 3.10.

Driver short name

AVIF

Build dependencies

libavif

AV1 Image File Format (AVIF) is an open, royalty-free image file format specification for storing images or image sequences compressed with AV1 in the HEIF container format.

It supports 8-bit, 10-bit and 12-bit images, single-bland, single-band and alpha channel, RGB and RGBA.

Files containing animations (several images) will be exposed as GDAL subdatasets.

Compression and decompression is done on entire images, so the driver can not handle arbitrary sizes images.

Note: read-only support for AVIF files is also available through the *HEIF / HEIC -- ISO/IEC 23008-12 High Efficiency Image File Format* driver if the AVIF driver is not available, and if libheif has been compiled with an AV1 compatible decoder.

6.6.1 Driver capabilities

Supports VirtualIO

This driver supports *virtual I/O operations (/vsimem/, etc.)*

Supports CreateCopy()

This driver supports the *GDALDriver::CreateCopy()* operation

Supports Georeferencing

This driver supports georeferencing

6.6.2 Color Profile Metadata

GDAL can deal with the following color profile metadata in the COLOR_PROFILE domain:

- SOURCE_ICC_PROFILE (Base64 encoded ICC profile embedded in file.)

6.6.3 Georeferencing

AVIF provides experimental read-only support for GeoHEIF internal referencing, based on the draft OGC 24-038 design. There is no support for writing at this time.

This requires at least libavif 1.2.0 (currently unreleased).

6.6.4 Creation options

Creation options can be specified in command-line tools using the syntax `-co <NAME>=<VALUE>` or by providing the appropriate arguments to *GDALCreate()* (C) or *Driver.Create* (Python). The following creation options are supported:

- **CODEC=[AUTO/AOM/RAV1E/SVT]:** Defaults to `AUTO`. Compression library to use. Choices available depend on how libavif has been built.
- **QUALITY=[0-100]:** Defaults to `60`. Quality for non-alpha channels. 0 is the lowest quality, 100 is for lossless encoding. Default is 60.
- **QUALITY_ALPHA=[0-100]:** Defaults to `100`. Quality for alpha channel. 0 is the lowest quality, 100 is for lossless encoding. Default is 100/lossless.
- **SPEED=[0-10]:** Defaults to `6`. Speed of encoding. 0=slowest. 10=fastest.
- **NUM_THREADS=<integer>|ALL_CPUS:** Defaults to `ALL_CPUS`. Number of worker threads for compression.
- **SOURCE_ICC_PROFILE=value:** ICC profile encoded in Base64. Can also be set to empty string to avoid the ICC profile from the source dataset to be used.
- **WRITE_EXIF_METADATA=[YES/NO]:** Defaults to `YES`. Whether to write EXIF metadata present in source file.
- **WRITE_XMP=[YES/NO]:** Defaults to `YES`. Whether to write XMP metadata present in source file.
- **NBITS=[8/10/12/16]:** Bit depth. 16 only supported with libavif >= 1.4 and GDAL >= 3.13

- **YUV_SUBSAMPLING=[444/422/420]:** Defaults to 444. Type of *chroma subsampling <https://en.wikipedia.org/wiki/Chroma_subsampling>* to apply to YUV channels for RGB or RGBA images (it is ignored for single band of single band + alpha images) 4:4:4 corresponds to full horizontal and vertical resolution for chrominance channels. 4:2:2 corresponds to half horizontal and full vertical resolution. 4:2:0 corresponds to half horizontal and half vertical resolution. Only 4:4:4 can be used for lossless encoding.

6.6.5 See Also

- libavif

6.7 BAG -- Bathymetry Attributed Grid

Driver short name

BAG

Build dependencies

libhdf5

This driver provides read-only and creation support for bathymetry data in the BAG format. BAG files are actually a specific product profile in an HDF5 file, but a custom driver exists to present the data in a more convenient manner than is available through the generic HDF5 driver.

BAG files have two image bands representing Elevation (band 1), Uncertainty (band 2) values for each cell in a raster grid area. Nominal Elevation values may also be present, and starting with GDAL 3.2, any 2D array of numeric data type and with the same dimensions as Elevation present under BAG_root will be reported as a GDAL band.

The geotransform and coordinate system is extracted from the internal XML metadata provided with the dataset. However, some products may have unsupported coordinate system formats, if using the non-WKT way of encoding the spatial reference system.

The full XML metadata is available in the "xml:BAG" metadata domain.

Nodata, minimum and maximum values for each band are also reported.

6.7.1 Driver capabilities

Supports CreateCopy()

This driver supports the `GDALDriver::CreateCopy()` operation

Supports Create()

This driver supports the `GDALDriver::Create()` operation

Added in version 3.2.

Supports Georeferencing

This driver supports georeferencing

Supports VirtualIO

This driver supports *virtual I/O operations (/vsimem/, etc.)*

6.7.2 Open options

Open options can be specified in command-line tools using the syntax `-oo <NAME>=<VALUE>` or by providing the appropriate arguments to *`GDALOpenEx()`* (C) or *`gdal.OpenEx`* (Python). For open options specific to variable resolution, see following chapter.

Other open options are:

- **REPORT_VERTCRS=[YES/NO]:** (GDAL >= 3.2) Defaults to `YES`. To report the vertical CRS from BAG XML metadata as the vertical component of a compound CRS. If set to NO, only the horizontal part will be reported.

6.7.3 Variable resolution (VR) grid support

GDAL can handle BAG files with variable resolution grids. Such datasets are made of a low-resolution grid, which is the one presented by default by the driver, and for each of those low-resolution cells, a higher resolution grid can be present in the file. Such higher resolution grids are dubbed "supergrids" in GDAL.

The driver has different modes of working which can be controlled by the MODE open option:

MODE=[LOW_RES_GRID/LIST_SUPERGRIDS/RESAMPLED_GRID/INTERPOLATED/AUTO]: Defaults to `AUTO`. Driver mode.

- MODE=LOW_RES_GRID: this is the default mode (unless opening a supergrid). The driver will expose the low resolution grid, and indicate in the dataset metadata if the dataset has supergrids (HAS_SUPERGRIDS=TRUE), as well as the minimum and maximum resolution of those grids.
- MODE=LIST_SUPERGRIDS: in this mode, the driver will report the various supergrids in the subdataset list. It is possible to apply in this mode additional open options to restrict the search
  - **SUPERGRIDS_INDICES=<(y1,x1),(y2,x2),...>:** Tuple or list of tuples, of supergrids described by their y,x indices (starting from 0, y from the south of the grid, x from the west o the grid).
  - MINX=value: Minimum georeferenced X value to use as a filter for the supergrids to list.
  - MINY=value: Minimum georeferenced Y value to use as a filter for the supergrids to list.
  - MAXX=value: Maximum georeferenced X value to use as a filter for the supergrids to list.
  - MAXY=value: Maximum georeferenced Y value to use as a filter for the supergrids to list.
  - RES_FILTER_MIN=value: Minimum resolution of supergrids to take into account (excluded bound)
  - RES_FILTER_MAX=value: Maximum resolution of supergrids to take into account (included bound)
- Opening a supergrid. This mode is triggered by using as a dataset name a string formatted like BAG:my.bag:supergrid:{y}:{x}, which is the value of the SUBDATASET_x_NAME metadata items reported by the above described mode. {y} is the index (starting from 0, from the south of the grid), and {x} is the index (starting from 0, from the west of the grid) of the supergrid to open.

- MODE=RESAMPLED_GRID: in this mode, the user specify the extent and resolution of a target grid, and for each cell of this target grid, the driver will find the nodes of the supergrids that fall into that cell. By default, it will select the node with the maximum elevation value to populate the cell value. Or if no node of any supergrid are found, the cell value will be set to the nodata value. Overviews are reported: note that, those overviews correspond to resampled grids computed with different values of the RESX and RESY parameters, but using the same value population rules (and not nearest neighbour resampling of the full resolution resampled grid). The last overview level is the low-resolution grid (if SUPERGRIDS_MASK=NO)

  The available open options in this mode are:

  - MINX=value: Minimum georeferenced X value for the resampled grid. By default, the corresponding value of the low resolution grid.
  - MINY=value: Minimum georeferenced Y value for the resampled grid. By default, the corresponding value of the low resolution grid.
  - MAXX=value: Maximum georeferenced X value for the resampled grid. By default, the corresponding value of the low resolution grid.
  - MAXY=value: Maximum georeferenced Y value for the resampled grid. By default, the corresponding value of the low resolution grid.
  - RESX=value: Horizontal resolution. By default, and if RES_STRATEGY is set to AUTO, this will be the minimum resolution among all the supergrids.
  - RESY=value: Vertical resolution (positive value). By default, and if RES_STRATEGY is set to AUTO, this will be the minimum resolution among all the supergrids.
  - RES_STRATEGY=AUTO/MIN/MAX/MEAN: Which strategy to apply to set the resampled grid resolution. By default, if none of RESX, RESY, RES_FILTER_MIN and RES_FILTER_MAX is specified, the AUTO strategy will correspond to the MIN strategy: that is the minimum resolution among all the supergrids is used. If MAX is specified, the maximum resolution among all the supergrids is used. If MEAN is specified, the mean resolution among all the supergrids is used. RESX and RESY, if defined, will override the resolution determined by RES_STRATEGY.
  - RES_FILTER_MIN=value: Minimum resolution of supergrids to take into account (excluded bound, except if it is the minimum resolution of supergrids). By default, the minimum resolution of supergrids available. If this value is specified and none of RES_STRATEGY, RES_FILTER_MAX, RESX or RESY is specified, the maximum resolution among all the supergrids will be used as the resolution for the resampled grid.
  - RES_FILTER_MAX=value: Maximum resolution of supergrids to take into account (included bound). By default, the maximum resolution of supergrids available. If this value is specified and none of RES_STRATEGY, RESX or RESY is specified, this will also be used as the resolution for the resampled grid.
  - VALUE_POPULATION=MIN/MAX/MEAN/COUNT: Which value population strategy to apply to compute the resampled cell values. This default to MAX: the elevation value of a target cell is the maximum elevation of all supergrid nodes (potentially filtered with RES_FILTER_MIN and/or RES_FILTER_MAX) that fall into this cell; the corresponding uncertainty will be the uncertainty of the source node where this maximum elevation si reached. If no supergrid node fall into the target cell, the nodata value is set. The MIN strategy is similar, except that this is the minimum elevation value among intersecting nodes that is selected. The MEAN strategy uses the mean value of the elevation of intersecting nodes, and the maximum uncertainty of those nodes. The COUNT strategy (GDAL >= 3.2) exposes one single UInt32 band where each target cell contains the count of supergrid nodes that fall into it.
  - SUPERGRIDS_MASK=YES/NO. Default to NO. If set to YES, instead of the elevation and uncertainty band, the dataset contains a single Byte band which is boolean valued. For a target cell, if at least one supergrids nodes (potentially filtered with RES_FILTER_MIN and/or RES_FILTER_MAX) falls into the cell, the cell value is set at 255. Otherwise it is set at 0. This can be used to distinguish if elevation

values at nodata are due to no source supergrid node falling into them, or if that/those supergrid nodes were themselves at the nodata value.

  - NODATA_VALUE=value. Override the default value, which is usually 1000000.

- MODE=INTERPOLATED: (GDAL >= 3.8) in this mode, the user specify the extent and resolution of a target grid, and for each cell of this target grid, the driver will interpolate the value from the surrounding nodes of the supergrid(s) that applies to the cell, using in priority bilinear interpolation (for a node that falls within a supergrid and when all 4 surrounding nodes of the supergrid are not at nodata value), and fallbacks to barycentric interpolation or inverse distance weighting in other situations.

  Overviews are reported. Note that those overviews correspond to resampled grids computed with different values of the RESX and RESY parameters, but for performance reasons, the interpolation is still limited to the immediate neighbours of the target grid in the supergrid(s), which result in the equivalent of nearest-neighbour downsampling of the full resolution raster. The last overview level is the low-resolution grid.

  The available open options in this mode are MINX, MINY, MAXX, MAXY, RESX, RESY, RES_STRATEGY, RES_FILTER_MIN, RES_FILTER_MAX and NODATA_VALUE (cf their above description for the MODE=RESAMPLED_GRID)

6.7.4 Spatial metadata support

Starting with GDAL 3.2, GDAL can expose BAG files with spatial metadata.

When such spatial metadata is present, the subdataset list will include names of the form 'BAG:"{filename}":georef_metadata:{name_of_layer}' where `name_of_layer` is the name of a subgroup under `/BAG_root/Georef_metadata`

The values of the `keys` dataset under each metadata layer are used as the GDAL raster value. And the corresponding `values` dataset is exposed as a GDAL Raster Attribute Table associated to the GDAL raster band. If `keys` is absent, record 1 of `values` is assumed to be met for each elevation point that does not match the nodata value of the elevation band.

When variable resolution grids are present, the MODE=LIST_SUPERGRIDS open option will cause subdatasets of names of the form 'BAG:"{filename}":georef_metadata:{name_of_layer}:{y}:{x}' to be reported. When opening such a subdataset, the `varres_keys` dataset will be used to populate the GDAL raster value. If `varres_keys` is absent, record 1 of `values` is assumed to be met for each elevation point that does not match the nodata value of the variable resolution elevation band.

6.7.5 Tracking list support

When the dataset is opened in vector mode (ogrinfo, ogr2ogr, etc.), the tracking_list dataset will be reported as a OGR vector layer

6.7.6 Creation support

The driver can create a BAG dataset (without variable resolution extension) with the elevation and uncertainty bands from a source dataset. The source dataset must be georeferenced, and have one or two bands. The first band is assumed to be the elevation band, and the second band the uncertainty band. If the second band is missing, the uncertainty will be set to nodata.

The driver will instantiate the BAG XML metadata by using a template file, which is by default, bag_template.xml, found in the GDAL data definition files. This template contains variables, present as ${KEYNAME} or ${KEYNAME:default_value} in the XML file, that can be substituted by providing a creation option whose name is the VAR_ string prefixed to the key name.

Creation options can be specified in command-line tools using the syntax `-co <NAME>=<VALUE>` or by providing the appropriate arguments to *`GDALCreate()`* (C) or *`Driver.Create`* (Python). The following creation options are supported:

- **VAR_INDIVIDUAL_NAME=value:** Defaults to `unknown`. String to fill contact/CI_ResponsibleParty/individualName.
- **VAR_ORGANISATION_NAME=value:** Defaults to `unknown`. String to fill contact/CI_ResponsibleParty/organisationName.
- **VAR_POSITION_NAME=value:** Defaults to `unknown`. String to fill contact/CI_ResponsibleParty/positionName.
- **VAR_DATE=<YYYY-MM-DD>:** Defaults to `current` date. Value to fill dateStamp/Date.
- **VAR_VERT_WKT=value:** WKT string to fill referenceSystemInfo/MD_ReferenceSystem/referenceSystemIdentifier/RS_Identifi for the vertical coordinate reference system. If not provided, and if the input CRS is not a compound CRS, default to VERT_CS["unknown", VERT_DATUM["unknown", 2000]].
- **VAR_ABSTRACT=value:** Defaults to `<empty` string>. String to fill identificationInfo/abstract.
- **VAR_PROCESS_STEP_DESCRIPTION=value:** Defaults to `Generated` by GDAL x.y.z. String to fill dataQualityInfo/lineage/LI_Lineage/processStep/LI_ProcessStep/description.
- **VAR_DATETIME=<YYYY-MM-DDTHH:MM:SS>:** Defaults to `current` datetime. Value to fill dataQualityInfo/lineage/LI_Lineage/processStep/LI_ProcessStep/dateTime/DateTime.
- **VAR_RESTRICTION_CODE=<enumerated_value>:** Defaults to `otherRestrictions`. Value to fill metadataConstraints/MD_LegalConstraints/useConstraints/MD_RestrictionCode.
- **VAR_OTHER_CONSTRAINTS=value:** Defaults to `unknown`. String to fill metadataConstraints/MD_LegalConstraints/otherConstraints.
- **VAR_CLASSIFICATION=<enumerated_value>:** Defaults to `unclassified`. Value to fill metadataConstraints/MD_SecurityConstraints/classification/MD_ClassificationCode.
- **VAR_SECURITY_USER_NOTE=value:** Defaults to `none`. String to fill metadataConstraints/MD_SecurityConstraints/userNote.

Other required variables found in the template, such as RES, RESX, RESY, RES_UNIT, HEIGHT, WIDTH, CORNER_POINTS and HORIZ_WKT will be automatically filled from the input dataset metadata.

The other following creation options are available:

- **TEMPLATE=<filename>:** Path to a XML file that can serve as a template. This will typically be a customized version of the base bag_template.xml file. The file can contain other substitutable variables than the ones mentioned above by using a similar syntax.
- **VAR_xxxx=value:** Substitute variable `${xxxx}` in the template XML value by the provided value.
- **BAG_VERSION=value:** Defaults to `1.6.2`. Value to write in the /BAG_root/BAG Version attribute.
- **COMPRESS=[NONE/DEFLATE]:** Defaults to `DEFLATE`. Compression for elevation and uncertainty grids.
- **ZLEVEL=1-9:** Defaults to `6`. Deflate compression level.
- **BLOCK_SIZE=<integer>:** Chunking size of the HDF5 arrays. Default to 100, or the maximum dimension of the raster if smaller than 100.

6.7.7 Usage examples

- Opening in low resolution mode:

```
$ gdalinfo data/test_vr.bag

[...]
Size is 6, 4
```

(continues on next page)

(continued from previous page)

```
[...]
  HAS_SUPERGRIDS=TRUE
  MAX_RESOLUTION_X=29.900000
  MAX_RESOLUTION_Y=31.900000
  MIN_RESOLUTION_X=4.983333
  MIN_RESOLUTION_Y=5.316667
[...]
```

- Displaying available supergrids:

```
$ gdalinfo data/test_vr.bag -oo MODE=LIST_SUPERGRIDS

[...]
Subdatasets:
  SUBDATASET_1_NAME=BAG:"data/test_vr.bag":supergrid:0:0
  SUBDATASET_1_DESC=Supergrid (y=0, x=0) from (x=70.100000,y=499968.100000) to␣
↪(x=129.900000,y=500031.900000), resolution (x=29.900000,y=31.900000)
  SUBDATASET_2_NAME=BAG:"data/test_vr.bag":supergrid:0:1
  SUBDATASET_2_DESC=Supergrid (y=0, x=1) from (x=107.575000,y=499976.075000) to␣
↪(x=152.424999,y=500023.924999), resolution (x=14.950000,y=15.950000)
[...]
  SUBDATASET_24_NAME=BAG:"data/test_vr.bag":supergrid:3:5
  SUBDATASET_24_DESC=Supergrid (y=3, x=5) from (x=232.558335,y=500077.391667) to␣
↪(x=267.441666,y=500114.608334), resolution (x=4.983333,y=5.316667)
[...]
```

- Opening a particular supergrid:

```
$ gdalinfo BAG:"data/test_vr.bag":supergrid:3:5
```

- Converting a BAG in resampling mode with default parameters (use of minimum resolution of supergrids, MAX value population rule):

```
$ gdal_translate data/test_vr.bag -oo MODE=RESAMPLED_GRID out.tif
```

- Converting a BAG in resampling mode with a particular grid origin and resolution

```
$ gdal_translate data/test_vr.bag -oo MODE=RESAMPLED_GRID -oo MINX=80 -oo␣
↪MINY=500000 -oo RESX=16 -oo RESY=16 out.tif
```

- Converting a BAG in resampling mode, with a mask indicating where supergrids nodes intersect the cell of the resampled dataset.

```
$ gdal_translate data/test_vr.bag -oo MODE=RESAMPLED_GRID -oo SUPERGRIDS_MASK=YES␣
↪out.tif
```

- Converting a BAG in resampling mode, by filtering on supergrid resolutions (and the resampled grid will use 4 meter resolution by default)

```
$ gdal_translate data/test_vr.bag -oo MODE=RESAMPLED_GRID -oo RES_FILTER_MIN=4 -oo␣
↪RES_FILTER_MAX=8 out.tif
```

- Converting a GeoTIFF file to a BAG dataset, and provide a custom value for the ABSTRACT substitutable variable.

```
$ gdal_translate in.tif out.bag -co "VAR_ABSTRACT=My abstract"
```

- Converting a (VR) BAG in resampling mode with a particular grid resolution (5m) to a BAG dataset (without variable resolution extension), and provide a custom value for the ABSTRACT metadata:

```
$ gdal_translate data/test_vr.bag -oo MODE=RESAMPLED_GRID -oo RESX=5 -oo RESY=5 out.
↪bag -co "VAR_ABSTRACT=My abstract"
```

- Displaying the tracking list:

```
$ ogrinfo -al data/my.bal
```

6.8 BASISU -- Basis Universal

Added in version 3.6.

Driver short name

BASISU

Build dependencies

Basis Universal

From https://github.com/BinomialLLC/basis_universal,

> Basis Universal is a "supercompressed" GPU texture data interchange system that supports two highly compressed intermediate file formats (.basis or the .KTX2 open standard from the Khronos Group) that can be quickly transcoded to a very wide variety of GPU compressed and uncompressed pixel formats.

This driver handles textures with the .basis extension. For KTX2, refer to the *KTX2* driver.

Note that while the file format supports direct transcoding to other GPU pixel formats, this GDAL driver supports only conversion between uncompressed RGB(A) data and Basis Universal textures.

When a file is made of several images, they are exposed as subdataset, with the *BASISU:filename:image_idx* syntax.

Mipmaps levels are exposed as GDAL overviews.

6.8.1 Driver capabilities

Supports CreateCopy()

This driver supports the *GDALDriver::CreateCopy()* operation

Supports VirtualIO

This driver supports *virtual I/O operations (/vsimem/, etc.)*

6.8.2 Creation options

The format supports 2 modes: a high quality mode which is internally based off the UASTC compressed texture format, and the original lower quality mode which is based off a subset of ETC1 called "ETC1S". The default is ETC1S. Only input of type Byte and with 1 (grey), 2 (grey+alpha), 3 (RGB) or 4 (RGB + alpha) bands is supported. Refer to https://github.com/BinomialLLC/basis_universal for more details on those modes and their options.

Creation options can be specified in command-line tools using the syntax `-co <NAME>=<VALUE>` or by providing the appropriate arguments to *GDALCreate()* (C) or *Driver.Create* (Python). The following creation options are available:

- **COMPRESSION=[ETC1S/UASTC]:** Defaults to `ETC1S`.
- **UASTC_LEVEL=[0/1/2/3/4]:** Defaults to `2`. The higher value, the higher the quality but the slower computing time. 4 is impractically slow. Only valid when *COMPRESSION=UASTC*.
- **UASTC_RDO_LEVEL=<float>:** Defaults to `1.0`. Rate distortion optimization level. The lower value, the higher the quality, but the larger the file size. Usual range is [0.2,3]. Only valid when *COMPRESSION=UASTC*.
- **ETC1S_LEVEL=[0/1/2/3/4/5/6]:** Defaults to `1`. The higher value, the higher the quality but the slower computing time. Only valid when *COMPRESSION=ETC1S*.
- **ETC1S_QUALITY_LEVEL=[<integer in [1/255] range>]:** Defaults to `128`. The higher value, the higher the quality, but the larger the file size. Only valid when *COMPRESSION=ETC1S*.
- **ETC1S_MAX_ENDPOINTS_CLUSTERS=[<integer in [1/16128] range>]:** Maximum number of endpoint clusters. When set, *ETC1S_MAX_SELECTOR_CLUSTERS* must also be set. Mutually exclusive with *ETC1S_QUALITY_LEVEL*. Only valid when *COMPRESSION=ETC1S*.
- **ETC1S_MAX_SELECTOR_CLUSTERS=[<integer in [1/16128] range>]:** Maximum number of selector clusters. When set, *ETC1S_MAX_ENDPOINTS_CLUSTERS* must also be set. Mutually exclusive with *ETC1S_QUALITY_LEVEL*. Only valid when *COMPRESSION=ETC1S*.
- **NUM_THREADS=<integer>:** Defaults to the maximum number of virtual CPUs available. Can also be controlled with the *GDAL_NUM_THREADS* configuration option.
- **MIPMAP=[YES/NO]:** Defaults to `NO`. Whether to enable MIPMAP generation.
- **COLORSPACE=[PERCEPTUAL_SRGB/LINEAR]:** Defaults to `PERCEPTUAL_SRGB`. For non-photometric input, use LINEAR to avoid unnecessary artifacts.

6.8.3 Build instructions

Building basisu as a library requires currently building the *cmake* branch of the https://github.com/rouault/basis_universal/tree/cmake fork.

```
git clone -b cmake https://github.com/rouault/basis_universal
cd basis_universal
mkdir build
cd build
cmake .. -DCMAKE_INSTALL_PREFIX=/path/to/install-basisu -DCMAKE_BUILD_TYPE=Release -
↪DBUILD_SHARED_LIBS=ON
cmake --build . --config Release --target install
```

Once basisu is built, GDAL CMake options must be configured by pointing the basisu install prefix in the `CMAKE_PREFIX_PATH` variable or `basisu_ROOT` variable.

6.9 BMP -- Microsoft Windows Device Independent Bitmap

Driver short name

BMP

Driver built-in by default

This driver is built-in by default

MS Windows Device Independent Bitmaps supported by the Windows kernel and mostly used for storing system decoration images. Due to the nature of the BMP format it has several restrictions and could not be used for general image storing. In particular, you can create only 1-bit monochrome, 8-bit pseudocoloured and 24-bit RGB images only. Even grayscale images must be saved in pseudocolour form.

This driver supports reading almost any type of the BMP files and could write ones which should be supported on any Windows system. Only single- or three- band files could be saved in BMP file. Input values will be resampled to 8 bit.

If an ESRI world file exists with the .bpw, .bmpw or .wld extension, it will be read and used to establish the geotransform for the image.

6.9.1 Driver capabilities

Supports CreateCopy()

This driver supports the *GDALDriver::CreateCopy()* operation

Supports Create()

This driver supports the *GDALDriver::Create()* operation

Supports Georeferencing

This driver supports georeferencing

Supports VirtualIO

This driver supports *virtual I/O operations (/vsimem/, etc.)*

6.9.2 Creation Options

Creation options can be specified in command-line tools using the syntax `-co <NAME>=<VALUE>` or by providing the appropriate arguments to *`GDALCreate()`* (C) or *`Driver.Create`* (Python). The following creation options are supported:

- **WORLDFILE=YES:** Force the generation of an associated ESRI world file (with the extension .wld).

6.9.3 See Also

- Implemented as bmpdataset.cpp.
- Wikipedia BMP file format

6.10 BSB -- Maptech/NOAA BSB Nautical Chart Format

Driver short name

BSB

Driver built-in by default

This driver is built-in by default

BSB Nautical Chart format is supported for read access, including reading the colour table and the reference points (as GCPs). Note that the .BSB files cannot be selected directly. Instead select the .KAP files. Versions 1.1, 2.0 and 3.0 have been tested successfully.

This driver should also support GEO/NOS format as supplied by Softchart. These files normally have the extension .nos with associated .geo files containing georeferencing ... the .geo files are currently ignored.

This driver is based on work by Mike Higgins. See the bsb_read.c files for details on patents affecting BSB format.

It is possible to select an alternate color palette via the BSB_PALETTE configuration option. The default value is RGB. Other common values that can be found are : DAY, DSK, NGT, NGR, GRY, PRC, PRG...

NOTE: Implemented as bsbdataset.cpp.

6.10.1 Driver capabilities

Supports Georeferencing

This driver supports georeferencing

Supports VirtualIO

This driver supports *virtual I/O operations (/vsimem/, etc.)*

6.10.2 Metadata

The following metadata items may be reported:

- **BSB_KNP**: content of the KNP/ header field, giving information on the coordinate reference system.
- **BSB_KNQ**: content of the KNQ/ header field, giving information on the coordinate reference system.
- **BSB_CUTLINE**: (starting with GDAL 3.1). When PLY/ header is present, Well-Known text representation of a polygon with coordinates in longitude, latitude order, representing the cutline of the chart.

6.11 BT -- VTP .bt Binary Terrain Format

Driver short name

BT

Driver built-in by default

This driver is built-in by default

The .bt format is used for elevation data in the VTP software. The driver includes support for reading and writing .bt 1.3 format including support for Int16, Int32 and Float32 pixel data types.

The driver does **not** support reading or writing gzipped (.bt.gz) .bt files even though this is supported by the VTP software. Please unpack the files before using with GDAL using the "gzip -d file.bt.gz".

Projections in external .prj files are read and written, and support for most internally defined coordinate systems is also available.

Read/write imagery access with the GDAL .bt driver is terribly slow due to a very inefficient access strategy to this column oriented data. This could be corrected, but it would be a fair effort.

NOTE: Implemented as btdataset.cpp.

See Also: The BT file format is defined on the VTP web site.

6.11.1 Driver capabilities

Supports CreateCopy()

This driver supports the `GDALDriver::CreateCopy()` operation

Supports Create()

This driver supports the `GDALDriver::Create()` operation

Supports Georeferencing

This driver supports georeferencing

Supports VirtualIO

This driver supports *virtual I/O operations (/vsimem/, etc.)*

6.12 BYN - Natural Resources Canada's Geoid file format (.byn)

Driver short name

BYN

Driver built-in by default

This driver is built-in by default

Files with extension ".byn" have a binary format. The format includes two sections which are the Header and the Data. The data are stored by rows starting from the north. Each row is stored from the west to the east. The data are either short (2 bytes) or standard (4 bytes) integers. The size of the bytes is defined in the header.

The total size of the file is 80 bytes + (Row x Column x (2 or 4) bytes) where Row is the number of rows in the grid and Column is the number of columns in the grid. Row and Column can be calculated by these two equations:

Row = (North Boundary - South Boundary) / (NS Spacing) + 1

Column = (East Boundary - West Boundary) / (EW Spacing) + 1

The ".byn" files may contain undefined data. Depending if the data are stored as 2-byte or 4-byte integers, the undefined data are expressed the following way:

4-byte data (Standard integer): 9999.0 * Factor, the Factor is given in the header

2 byte data (Short integer): 32767

Most of the parameters in the ".byn" header can be read by clicking the “Information” icon in software GPS-H.

NOTE: Files with extension ".err" are also in the ".byn" format. An ".err" file usually contains the error estimates of the ".byn" file of the same name (e.g., CGG2013n83.byn and CGG2013n83.err). The ".err" file will have variable Data equal to 1 or 3.

6.12.1 Driver capabilities

Supports Georeferencing

This driver supports georeferencing

Supports VirtualIO

This driver supports *virtual I/O operations (/vsimem/, etc.)*

6.12.2 Factor

When translating from BYN file to or from another formats the scale will affect the result profoundly.

Translating to a format that supports Scale (GTIFF for example) will maintain the data type and thescale information. The pixel values are perfectly preserved.

Translating to a format that does not support Scale will maintain the data type but without the Scale, meaning loss of information on every pixels.

The solution to the problem above is to use "-unscale" and "-ot Float32" when using gdal_translate or GDAL API. That will produce a dataset without scale but with the correct pixel information. Ex.:

gdal_translate CGG2013an83.err test2.tif -unscale -ot Float32

NOTE: The BYN header variable **Factor** is the inverse of GDAL **Scale**. (Scale = 1.0 / Factor).

6.12.3 See Also

- Implemented as byndataset.cpp.
- www.nrcan.gc.ca

6.13 CAD -- AutoCAD DWG raster layer

Driver short name

CAD

Build dependencies

(internal libopencad provided)

OGR DWG support is based on libopencad, so the list of supported DWG (DXF) versions can be seen in libopencad documentation. All drawing entities are separated into layers as they are in DWG file. The rasters are usually a separate georeferenced files (GeoTiff, Jpeg, Png etc.) which exist in DWG file as separate layers. The driver try to get spatial reference and other methadata from DWG Image description and set it to GDALDataset.

NOTE: Implemented as gdalcaddataset.cpp.

6.13.1 Driver capabilities

Supports Georeferencing

This driver supports georeferencing

Supports VirtualIO

This driver supports *virtual I/O operations (/vsimem/, etc.)*

6.14 CALS -- CALS Type 1

Driver short name

CALS

Driver built-in by default

This driver is built-in by default

CALS Type 1 rasters are untiled black and white rasters made of a 2048-byte text header in the MIL-STD-1840 standard, followed by a single datastream compressed with CCITT/ITU-T Recommendation 6, aka Group 6, aka CCITT FAX 4. CALS Type 1 rasters are one of the 4 types of formats described by MIL-PRF-28002C (this standard is now deprecated). Other types are not handled by this driver.

This driver supports reading and creation of CALS Type 1 rasters. Update of existing rasters is not supported.

A CALS dataset is exposed by the driver as a single-band 1-bit raster with a 2-entry color table. The first entry (0) is white (RGB=255,255,255) and the second entry (1) is black (RGB=0,0,0).

6.14.1 Driver capabilities

Supports CreateCopy()

This driver supports the `GDALDriver::CreateCopy()` operation

Supports VirtualIO

This driver supports *virtual I/O operations (/vsimem/, etc.)*

6.14.2 Metadata

The following metadata items might be exposed by the driver (or read from the input dataset to generate a cor

- **PIXEL_PATH**: First value of the "rorient" header field, measured in degrees counterclockwise from the positive horizontal axis (east). The pel path value represents the number of degrees the image would have to be rotated counterclockwise in order to display the image with proper viewing orientation. The permissible values for the pixel path direction shall be "0", "90", "180", or "270". 0 is the typical value. If PIXEL_PATH=0 and LINE_PROGRESSION=270, neither are reported.
- **LINE_PROGRESSION**: Second value of the "rorient" header field. The line progression direction is measured in degrees counterclockwise from the pel path direction. The permissible values for the line progression direction shall be "90" or "270". 270 is the typical value. If PIXEL_PATH=0 and LINE_PROGRESSION=270, neither are reported.

- **TIFFTAG_XRESOLUTION**: Scan X resolution in dot per inch, from the "rdensty" header field. TIFFTAG_XRESOLUTION and TIFFTAG_YRESOLUTION are always equal in CALS.
- **TIFFTAG_YRESOLUTION**: Scan Y resolution in dot per inch, from the "rdensty" header field. TIFFTAG_XRESOLUTION and TIFFTAG_YRESOLUTION are always equal in CALS.

6.14.3 Creation issues

Only single band 1-bit rasters are valid input to create a new CALS file. If the input raster has no color table, 0 is assumed to be black and 1 to be white. If the input raster has a (2 entries) color table, the value for the black and white color will be determined from the color table.

6.15 CEOS -- CEOS Image

Driver short name

CEOS

Driver built-in by default

This driver is built-in by default

This is a simple, read-only reader for ceos image files. To use, select the main imagery file. This driver reads only the image data, and does not capture any metadata, or georeferencing.

This driver is known to work with CEOS data produced by Spot Image, but will have problems with many other data sources. In particular, it will only work with eight bit unsigned data.

See the separate *SAR_CEOS -- CEOS SAR Image* driver for access to SAR CEOS data products.

NOTE: Implemented as ceosdataset.cpp.

6.15.1 Driver capabilities

Supports VirtualIO

This driver supports *virtual I/O operations (/vsimem/, etc.)*

6.16 COASP -- DRDC COASP SAR Processor Raster

Driver short name

COASP

Driver built-in by default

This driver is built-in by default

NOTE: Implemented as coasp_dataset.cpp.

6.17 COG -- Cloud Optimized GeoTIFF generator

Added in version 3.1.

Driver short name

COG

Driver built-in by default

This driver is built-in by default

This driver supports the creation of Cloud Optimized GeoTIFF (COG)

It essentially relies upon the *GTiff -- GeoTIFF File Format* driver with the `COPY_SRC_OVERVIEWS=YES` creation option, but automatically does the needed preprocessing stages (reprojection if asked and creation of overviews on imagery and/or mask) if not already done, and also takes care of morphing the input dataset into the expected form when using some compression types (for example a RGBA dataset will be transparently converted to a RGB+mask dataset when selecting JPEG compression)

This driver is nominally used through the *`GDALDriver::CreateCopy()`* method, that natively does not support random writing but requires a source dataset to be provided as input. During the writing process, if overviews are generated, they will be created in a temporary dataset, requiring storage capacity of roughly one third of the final file size, before being transferred to the output file. By default temporary files are created in the same directory as the final file, if the target file system supports random writing and if the *`CPL_TMPDIR`* configuration option is not set.

Starting with GDAL 3.13, the *`GDALDriver::Create()`* method is also implemented, by using a temporary GeoTIFF dataset, which means that at least twice the final size of the file of storage capacity is required. Note that as the temporary dataset uses lossless compression, if the final COG file uses lossy compression, more temporary storage may be needed.

Validation whether a TIFF file is a valid COG file can be done with *gdal driver cog validate*.

6.17.1 Driver capabilities

Supports Create()

Added in version 3.13.

Supports CreateCopy()

This driver supports the *`GDALDriver::CreateCopy()`* operation

Supports Georeferencing

This driver supports georeferencing

Supports VirtualIO

This driver supports *virtual I/O operations (/vsimem/, etc.)*

6.17.2 Creation Options

Creation options can be specified in command-line tools using the syntax `-co <NAME>=<VALUE>` or by providing the appropriate arguments to *`GDALCreate()`* (C) or *`Driver.Create`* (Python).

6.17.2.1 General creation options

- **BLOCKSIZE=<integer>:** Defaults to `512`. Sets the tile width and height in pixels. Must be divisible by 16.
- **INTERLEAVE=[BAND/PIXEL/TILE]:** (GDAL >= 3.11) Set the interleaving to use. See *Multiband pixel organization (INTERLEAVE metadata item)* for more details.
  - `PIXEL`: for each spatial block, one TIFF tile/strip gathering values for all bands is used . This matches the `contiguous` planar configuration in TIFF terminology. This is also known as a `BIP (Band Interleaved Per Pixel)` organization. Such method is the default, and may be slightly less efficient than BAND interleaving for some purposes, but some applications only support pixel interleaved TIFF files. On the other hand, image-based compression methods may perform better using PIXEL interleaving. For JPEG PHOTOMETRIC=YCbCr, pixel interleaving is required. It is also required for WebP compression.

    Prior to GDAL 3.11, INTERLEAVE=PIXEL was the only possible interleaving output by the COG driver.

    Assuming a pixel[band][y][x] indexed array, when using CreateCopy(), the pseudo code for the file disposition is:

```
for y in 0 ... numberOfBlocksInHeight - 1:
    for x in 0 ... numberOfTilesInWidth - 1:
        for j in 0 ... blockHeight - 1:
            for i in 0 ... blockWidth -1:
                start_new_strip_or_tile()
                for band in 0 ... numberBands -1:
                    write(pixel[band][y*blockHeight+j][x*blockWidth+i])
                end_new_strip_or_tile()
            end_for
        end_for
    end_for
end_for
```

  - `BAND`: for each spatial block, one TIFF tile/strip is used for each band. This matches the contiguous `separate` configuration in TIFF terminology. This is also known as a `BSQ (Band SeQuential)` organization.

    In addition to that, when using CreateCopy(), data for the first band is written first, followed by data for the second band, etc. The pseudo code for the file disposition is:

```
for y in 0 ... numberOfBlocksInHeight - 1:
    for x in 0 ... numberOfTilesInWidth - 1:
```

(continues on next page)

(continued from previous page)

```
        start_new_strip_or_tile()
        for band in 0 ... numberBands -1:
            for j in 0 ... blockHeight - 1:
                for i in 0 ... blockWidth -1:
                    write(pixel[band][y*blockHeight+j][x*blockWidth+i])
                end_for
            end_for
        end_new_strip_or_tile()
    end_for
end_for
```

- TILE (added in 3.11): this is a sort of compromise between PIXEL and BAND, using the separate configuration, but where data for a same spatial block is written for all bands, before the data of the next spatial block. When the block height is 1, this is also known as a BIL (Band Interleaved per Line) organization.

  Such a layout may be useful for writing hyperspectral datasets (several hundred of bands), to get a compromise between efficient spatial query, and partial band selection.

  Assuming a pixel[band][y][x] indexed array, when using CreateCopy(), the pseudo code for the file disposition is:

```
for y in 0 ... numberOfBlocksInHeight - 1:
    for x in 0 ... numberOfTilesInWidth - 1:
        for band in 0 ... numberBands -1:
            start_new_strip_or_tile()
            for j in 0 ... blockHeight - 1:
                for i in 0 ... blockWidth -1:
                    write(pixel[band][y*blockHeight+j][x*blockWidth+i])
                end_for
            end_for
            end_new_strip_or_tile()
        end_for
    end_for
end_for
```

Starting with GDAL 3.5, when copying from a source dataset with multiple bands which advertises a INTERLEAVE metadata item, if the INTERLEAVE creation option is not specified, the source dataset INTERLEAVE will be automatically taken into account, unless the COMPRESS creation option is specified.

- **COMPRESS=[NONE/LZW/JPEG/DEFLATE/ZSTD/WEBP/LERC/LERC_DEFLATE/LERC_ZSTD/LZMA]:** Defaults to LZW. Set the compression to use. Defaults to LZW starting with GDAL 3.4 (default in previous version is NONE).
  - JPEG should generally only be used with Byte data (8 bit per channel). But if GDAL is built with internal libtiff and libjpeg, it is possible to read and write TIFF files with 12bit JPEG compressed TIFF files (seen as UInt16 bands with NBITS=12). For the COG driver, JPEG compression for 3 or 4-band images automatically selects the PHOTOMETRIC=YCBCR colorspace with a 4:2:2 subsampling of the Y,Cb,Cr components with the default INTERLEAVE=PIXEL. For a input dataset (single-band or 3-band), plus an alpha band, the alpha band will be converted as a 1-bit DEFLATE compressed mask.
  - LZW, DEFLATE and ZSTD compressions can be used with the PREDICTOR creation option.
  - ZSTD is available when using internal libtiff and if GDAL built against libzstd >=1.0, or if built against external libtiff with zstd support.

  - `WEBP` is available when using internal libtiff and if GDAL built against libwebp, or if built against external libtiff with WebP support. It can only be used with the default INTERLEAVE=PIXEL.
  - `LERC` is available when using internal libtiff.
  - `LERC_ZSTD` is available when `LERC` and `ZSTD` are available.
  - `JXL` is for JPEG-XL, and is only available when using internal libtiff and building GDAL against https://github.com/libjxl/libjxl . JXL compression may only be used on datasets with 4 bands or less. Option added in GDAL 3.4

- **LEVEL=<integer>:** DEFLATE/ZSTD/LERC_DEFLATE/LERC_ZSTD/LZMA compression level. A lower number will result in faster compression but less efficient compression rate. 1 is the fastest.
  - For DEFLATE/LZMA, 9 is the slowest/higher compression rate (or 12 when using a libtiff with libdeflate support). The default is 6.
  - For ZSTD, 22 is the slowest/higher compression rate. The default is 9.
- **MAX_Z_ERROR=<threshold>:** Defaults to `0`. Set the maximum error threshold on values for LERC/LERC_DEFLATE/LERC_ZSTD compression. The default is 0 (lossless).
- **MAX_Z_ERROR_OVERVIEW=<threshold>:** (GDAL >= 3.8) Set the maximum error threshold on values for LERC/LERC_DEFLATE/LERC_ZSTD compression, on overviews. The default is the value of *MAX_Z_ERROR*
- **QUALITY=<integer>:** Defaults to `75`. JPEG/WEBP quality setting. A value of 100 is best quality (least compression), and 1 is worst quality (best compression). For WEBP, QUALITY=100 automatically turns on lossless mode.
- **JXL_LOSSLESS=[YES/NO]:** Defaults to `YES`. Set whether JPEG-XL compression should be lossless (YES) or lossy (NO). For lossy compression, the underlying data should be either gray, gray+alpha, rgb or rgb+alpha.
- **JXL_EFFORT=1-9:** Defaults to `5`. Level of effort for JPEG-XL compression. The higher, the smaller file and slower compression time.
- **JXL_DISTANCE=0.01-25:** Defaults to `1.0`. (Only applies when JXL_LOSSLESS=NO) Distance level for lossy JPEG-XL compression. It is specified in multiples of a just-noticeable difference (cf butteraugli for the definition of the distance) That is, 0 is mathematically lossless, 1 should be visually lossless, and higher distances yield denser and denser files with lower and lower fidelity. The recommended range is [0.5,3].
- **JXL_ALPHA_DISTANCE=[-1/0/0.01-25]:** (GDAL >= 3.7) Defaults to `-1`. (Only applies when JXL_LOSSLESS=NO) (libjxl > 0.8.1) Distance level for alpha channel for lossy JPEG-XL compression. It is specified in multiples of a just-noticeable difference. (cf butteraugli for the definition of the distance) That is, 0 is mathematically lossless, 1 should be visually lossless, and higher distances yield denser and denser files with lower and lower fidelity. For lossy compression, the recommended range is [0.5,3]. The default value is the special value -1.0, which means to use the same distance value as non-alpha channel (ie *JXL_DISTANCE*).
- **NUM_THREADS=[<number_of_threads>/ALL_CPUS]:** Enable multi-threaded compression by specifying the number of worker threads. Default is compression in the main thread. This also determines the number of threads used when reprojection is done with the *TILING_SCHEME* or *TARGET_SRS* creation options. (Overview generation is also multithreaded since GDAL 3.2)
- **NBITS=<integer>:** (GDAL >= 3.7) Create a file with less than 8 bits per sample by passing a value from 1 to 7. The apparent pixel type should be Byte. Values of n=9...15 (UInt16 type) and n=17...31 (UInt32 type) are also accepted. n=16 is accepted for Float32 type to generate half-precision floating point values.
- **PREDICTOR=[YES/NO/STANDARD/FLOATING_POINT]:** Defaults to `NO`. Set the predictor for LZW, DEFLATE and ZSTD compression. If YES is specified, then standard predictor (Predictor=2) is used for integer data type, and floating-point predictor (Predictor=3) for floating point data type (in some circumstances, the standard predictor might perform better than the floating-point one on floating-point data). STANDARD or FLOATING_POINT can also be used to select the precise algorithm wished.

- **BIGTIFF=[YES/NO/IF_NEEDED/IF_SAFER]:** Control whether the created file is a BigTIFF or a classic TIFF.
  - `YES` forces BigTIFF.
  - `NO` forces classic TIFF.
  - `IF_NEEDED` will only create a BigTIFF if it is clearly needed (in the uncompressed case, and image larger than 4GB. So no effect when using a compression).
  - `IF_SAFER` will create BigTIFF if the resulting file *might* exceed 4GB. Note: this is only a heuristics that might not always work depending on compression ratios.

  BigTIFF is a TIFF variant which can contain more than 4GiB of data (size of classic TIFF is limited by that value). This option is available if GDAL is built with libtiff library version 4.0 or higher. The default is IF_NEEDED.

  When creating a new GeoTIFF with no compression, GDAL computes in advance the size of the resulting file. If that computed file size is over 4GiB, GDAL will automatically decide to create a BigTIFF file. However, when compression is used, it is not possible in advance to known the final size of the file, so classical TIFF will be chosen. In that case, the user must explicitly require the creation of a BigTIFF with BIGTIFF=YES if the final file is anticipated to be too big for classical TIFF format. If BigTIFF creation is not explicitly asked or guessed and the resulting file is too big for classical TIFF, libtiff will fail with an error message like "TIFFAppendToStrip:Maximum TIFF file size exceeded".

- **RESAMPLING=[NEAREST/AVERAGE/BILINEAR/CUBIC/CUBICSPLINE/LANCZOS/MODE/RMS]:** Resampling method used for overview generation or reprojection. For paletted images, NEAREST is used by default, otherwise it is CUBIC.

- **OVERVIEW_RESAMPLING=[NEAREST/AVERAGE/BILINEAR/CUBIC/CUBICSPLINE/LANCZOS/MODE/RMS]:** (GDAL >= 3.2) Resampling method used for overview generation. For paletted images, NEAREST is used by default, otherwise it is CUBIC. This overrides, for overview generation, the value of *RESAMPLING* if it specified.

- **WARP_RESAMPLING=[NEAREST/AVERAGE/BILINEAR/CUBIC/CUBICSPLINE/LANCZOS/MODE/RMS/MIN/MAX/MED/Q1/Q3]:** (GDAL >= 3.2) Resampling method used for reprojection. For paletted images, NEAREST is used by default, otherwise it is CUBIC. This overrides, for reprojection, the value of *RESAMPLING* if it specified.

- **OVERVIEWS=[AUTO/IGNORE_EXISTING/FORCE_USE_EXISTING/NONE]:** Defaults to `AUTO`. Describe the behavior regarding overview generation and use of source overviews.
  - `AUTO` (default): source overviews will be used if present. If not present, overviews will be automatically generated in the output file.
  - `IGNORE_EXISTING`: potential existing overviews on the source dataset will be ignored and new overviews will be automatically generated.
  - `FORCE_USE_EXISTING`: potential existing overviews on the source will be used. If there is no source overview, this is equivalent to specifying `NONE`.
  - `NONE`: potential source overviews will be ignored, and no overview will be generated.

  > **Note**
  >
  > When using the gdal_translate utility, source overviews will not be available if general options (i.e. options which are not creation options, like subsetting, etc.) are used.

- **OVERVIEW_COUNT=<integer>:** (GDAL >= 3.6) Number of overview levels to generate. This can be used to increase or decrease the number of levels in the COG file (when GDAL computes overviews from the full resolution dataset, that is when there are no source overviews or the user specifies *OVERVIEWS=IGNORE_EXISTING*),

or decrease the number of levels copied from the source dataset (in *OVERVIEWS=AUTO* or FORCE_USE_EXISTING modes when there are such overviews in the source dataset). If not specified, the driver will use all the overviews available in the source raster, in *OVERVIEWS=AUTO* or FORCE_USE_EXISTING modes. In situations where GDAL generates overviews, the default number of overview levels is such that the dimensions of the smallest overview are smaller or equal to the *BLOCKSIZE* value.

- **OVERVIEW_COMPRESS=[AUTO/NONE/LZW/JPEG/DEFLATE/ZSTD/WEBP/LERC/LERC_DEFLATE/LERC_ZSTD/LZMA]:** Defaults to AUTO. Set the compression method (see COMPRESS) to use when storing the overviews in the COG. By default (AUTO) the overviews will be created with the same compression method as the COG.
- **OVERVIEW_QUALITY=<integer>:** JPEG/WEBP quality setting. A value of 100 is best quality (least compression), and 1 is worst quality (best compression). By default the overviews will be created with the same quality as the COG, unless the compression type is different then the default is 75.
- **OVERVIEW_PREDICTOR=[YES/NO/STANDARD/FLOATING_POINT]:** Set the predictor for LZW, DEFLATE and ZSTD overview compression. By default the overviews will be created with the same predictor as the COG, unless the compression type of the overview is different, then the default is NO.
- **GEOTIFF_VERSION=[AUTO/1.0/1.1]:** Defaults to AUTO. Select the version of the GeoTIFF standard used to encode georeferencing information. 1.0 corresponds to the original 1995, GeoTIFF Revision 1.0, by Ritter & Ruth. 1.1 corresponds to the OGC standard 19-008, which is an evolution of 1.0, which clear ambiguities and fix inconsistencies mostly in the processing of the vertical part of a CRS. AUTO mode (default value) will generally select 1.0, unless the CRS to encode has a vertical component or is a 3D CRS, in which case 1.1 is used.

> **Note**
>
> Write support for GeoTIFF 1.1 requires libgeotiff 1.6.0 or later.

- **SPARSE_OK=[TRUE/FALSE]:** (GDAL >= 3.2) Defaults to FALSE. Should empty blocks be omitted on disk? When this option is set, any attempt of writing a block whose all pixels are 0 or the nodata value will cause it not to be written at all (unless there is a corresponding block already allocated in the file). Sparse files have 0 tile/strip offsets for blocks never written and save space; however, most non-GDAL packages cannot read such files. On the reading side, the presence of a omitted tile after a non-empty one may cause optimized readers to have to issue an extra GET request to the TileByteCounts array.
- **STATISTICS=[AUTO/YES/NO]:** (GDAL >= 3.8) Defaults to AUTO. Whether band statistics should be included in the output file. In AUTO mode, they will be included only if available in the source dataset. If setting to YES, they will always be included. If setting to NO, they will be never included.

6.17.2.2 Reprojection related creation options

- **TILING_SCHEME=[CUSTOM/GoogleMapsCompatible/...]:** Defaults to CUSTOM. If set to a value different than CUSTOM, the definition of the specified tiling scheme will be used to reproject the dataset to its CRS, select the resolution corresponding to the closest zoom level and align on tile boundaries at this resolution (the actual resolution can be controlled with the *ZOOM_LEVEL* or *ZOOM_LEVEL_STRATEGY* options). The tile size indicated in the tiling scheme definition (generally 256 pixels) will be used, unless the user has specified a value with the *BLOCKSIZE* creation option, in which case the user specified one will be taken into account (that is if setting a higher value than 256, the original tiling scheme is modified to take into account the size of the HiDPi tiles).

  In non-CUSTOM mode, TARGET_SRS, RES and EXTENT options are ignored. Starting with GDAL 3.2, the value of *TILING_SCHEME* can also be the filename of a JSON file according to the *OGC Two Dimensional Tile Matrix Set standard*, a URL to such file, the radical of a definition file in the GDAL data directory (e.g. FOO for a file named tms_FOO.json) or the inline JSON definition. The list of available tiling schemes can be obtained by looking at values of the TILING_SCHEME option reported by gdalinfo --format COG.

- **ZOOM_LEVEL=<integer>:** (GDAL >= 3.5) Zoom level number (starting at 0 for coarsest zoom level). Only used for *TILING_SCHEME* different from CUSTOM. If this option is specified, *ZOOM_LEVEL_STRATEGY* is ignored.
- **ZOOM_LEVEL_STRATEGY=[AUTO/LOWER/UPPER]:** (GDAL >= 3.2) Defaults to `AUTO`. Strategy to determine zoom level. Only used for *TILING_SCHEME* different from CUSTOM. LOWER will select the zoom level immediately below the theoretical computed non-integral zoom level, leading to subsampling. On the contrary, UPPER will select the immediately above zoom level, leading to oversampling. Defaults to AUTO which selects the closest zoom level.
- **TARGET_SRS=value:** to force reprojection of the input dataset to another SRS. The string can be a WKT string, a EPSG:XXXX code or a PROJ string.
- **RES=value:** Set the resolution of the target raster, in the units of *TARGET_SRS*. Only taken into account if *TARGET_SRS* is specified.
- **EXTENT=<minx,miny,maxx,maxy>:** Set the extent of the target raster, in the units of *TARGET_SRS*. Only taken into account if *TARGET_SRS* is specified.
- **ALIGNED_LEVELS=<integer>:** Number of resolution levels for which GeoTIFF tile and tiles defined in the tiling scheme match. When specifying this option, padding tiles will be added to the left and top sides of the target raster, when needed, so that a GeoTIFF tile matches with a tile of the tiling scheme. Only taken into account if *TILING_SCHEME* is different from CUSTOM. Effect of this option is only visible when setting it at 2 or more, since the full resolution level is by default aligned with the tiling scheme. For a tiling scheme whose consecutive zoom level resolutions differ by a factor of 2, care must be taken in setting this value to a high number of levels, as up to 2^(ALIGNED_LEVELS-1) tiles can be added in each dimension. The driver enforces a hard limit of 10.
- **ADD_ALPHA=[YES/NO]:** Defaults to `YES`. Whether an alpha band is added in case of reprojection.

6.17.3 Update

Updating a COG file generally breaks part of the optimizations, but still produces a valid GeoTIFF file. Starting with GDAL 3.8, to avoid undesired loss of the COG characteristics, opening such a file in update mode will be rejected, unless the IGNORE_COG_LAYOUT_BREAK open option is also explicitly set to YES.

Note that a subset of operations are possible when opening a COG file in read-only mode, like metadata edition (including statistics storage), that will be stored in a auxiliary .aux.xml side-car file.

6.17.4 File format details

6.17.4.1 High level

A Cloud optimized GeoTIFF has the following characteristics:

- TIFF or BigTIFF file
- Tiled (512 pixels by default) for imagery, mask and overviews
- Overviews until the maximum dimension of the smallest overview level is lower than 512 pixels.
- Compressed or not
- Pixel interleaving for multi-band dataset
- Optimized layout of TIFF sections to minimize the number of GET requests needed by a reader doing random read access.

6.17.4.2 Low level

A COG file is organized as the following (if using libtiff >= 4.0.11 or GDAL internal libtiff. For other versions, the layout will be different and some of the optimizations will not be available).

- TIFF/BigTIFF header/signature and pointer to first IFD (Image File Directory)
- "ghost area" with COG optimizations (see *Header ghost area*)
- IFD of the full resolution image, followed by TIFF tags values, excluding the TileOffsets and TileByteCounts arrays.
- IFD of the mask of the full resolution image, if present, followed by TIFF tags values, excluding the TileOffsets and TileByteCounts arrays.
- IFD of the first (largest in dimensions) overview level, if present
- ...
- IFD of the last (smallest) overview level, if present
- IFD of the first (largest in dimensions) overview level of the mask, if present
- ...
- IFD of the last (smallest) overview level of the mask, if present
- TileOffsets and TileByteCounts arrays of the above IFDs
- tile data of the smallest overview, if present (with each tile followed by the corresponding tile of mask data, if present), with *leader and trailer bytes*
- ...
- tile data of the largest overview, if present (interleaved with mask data if present)
- tile data of the full resolution image, if present (interleaved with corresponding mask data if present)

6.17.4.3 Header ghost area

To describe the specific layout of COG files, a description of the features used is located at the beginning of the file, so that optimized readers (like GDAL) can use them and take shortcuts. Those features are described as ASCII strings "hidden" just after the 8 first bytes of a ClassicTIFF (or after the 16 first ones for a BigTIFF). That is the first IFD starts just after those strings. It is completely valid to have *ghost* areas like this in a TIFF file, and readers will normally skip over them. So for a COG file with a transparency mask, those strings will be:

```
GDAL_STRUCTURAL_METADATA_SIZE=000174 bytes
LAYOUT=IFDS_BEFORE_DATA
BLOCK_ORDER=ROW_MAJOR
BLOCK_LEADER=SIZE_AS_UINT4
BLOCK_TRAILER=LAST_4_BYTES_REPEATED
KNOWN_INCOMPATIBLE_EDITION=NO
MASK_INTERLEAVED_WITH_IMAGERY=YES
```

Note

- A newline character *n* is used to separate those strings.
- A space character is inserted after the newline following *KNOWN_INCOMPATIBLE_EDITION=NO*
- For a COG without mask, the *MASK_INTERLEAVED_WITH_IMAGERY* item will not be present of course.

The ghost area starts with `GDAL_STRUCTURAL_METADATA_SIZE=XXXXXX bytes\n` (of a fixed size of 43 bytes) where XXXXXX is a 6-digit number indicating the remaining size of the section (that is starting after the linefeed character of this starting line).

- `LAYOUT=IFDS_BEFORE_DATA`: the IFDs are located at the beginning of the file. GDAL will also makes sure that the tile index arrays are written just after the IFDs and before the imagery, so that a first range request of 16 KB will always get all the IFDs
- `BLOCK_ORDER=ROW_MAJOR`: (strile is a contraction of 'strip or tile') the data for tiles is written in increasing tile id order. Future enhancements could possibly implement other layouts.
- `BLOCK_LEADER=SIZE_AS_UINT4`: each tile data is preceded by 4 bytes, in a *ghost* area as well, indicating the real tile size (in little endian order). See *Tile data leader and trailer* for more details.
- `BLOCK_TRAILER=LAST_4_BYTES_REPEATED`: just after the tile data, the last 4 bytes of the tile data are repeated. See *Tile data leader and trailer* for more details.
- `KNOWN_INCOMPATIBLE_EDITION=NO`: when a COG is generated this is always written. If GDAL is then used to modify the COG file, as most of the changes done on an existing COG file, will break the optimized structure, GDAL will change this metadata item to KNOWN_INCOMPATIBLE_EDITION=YES, and issue a warning on writing, and when reopening such file, so that users know they have *broken* their COG file
- `MASK_INTERLEAVED_WITH_IMAGERY=YES`: indicates that mask data immediately follows imagery data. So when reading data at offset=TileOffset[i] - 4 and size=TileOffset[i+1]-TileOffset[i]+4, you'll get a buffer with:
  - leader with imagery tile size (4 bytes)
  - imagery data (starting at TileOffsets[i] and of size TileByteCounts[i])
  - trailer of imagery (4 bytes)
  - leader with mask tilesize (4 bytes)
  - mask data (starting at mask.TileOffsets[i] and of size mask.TileByteCounts[i], but none of them actually need to be read)
  - trailer of mask data (4 bytes)

  This is only written if INTERLEAVE=PIXEL.
- `INTERLEAVE=BAND` or `INTERLEAVE=TILE`: (GDAL >= 3.11) Reflects the value of the INTERLEAVE creation option. Omission implies INTERLEAVE=PIXEL.

> **Note**
>
> The content of the header ghost area can be retrieved by getting the `GDAL_STRUCTURAL_METADATA` metadata item of the `TIFF` metadata domain on the dataset object (with GetMetadataItem())

6.17.4.4 Tile data leader and trailer

Each tile data is immediately preceded by a leader, consisting of a unsigned 4-byte integer, in little endian order, giving the number of bytes of *payload* of the tile data that follows it. This leader is *ghost* in the sense that the TileOffsets[] array does not point to it, but points to the real payload. Hence the offset of the leader is TileOffsets[i]-4.

For INTERLEAVE=PIXEL or INTERLEAVE=TILE, an optimized reader seeing the `BLOCK_LEADER=SIZE_AS_UINT4` metadata item will thus look for TileOffset[i] and TileOffset[i+1] to deduce it must fetch the data starting at offset=TileOffset[i] - 4 and of size=TileOffset[i+1]-TileOffset[i]+4. It then checks the 4 first bytes to see if the size in this leader marker is consistent with TileOffset[i+1]-TileOffset[i]. When there is no mask, they should normally be equal (modulo the size taken by BLOCK_LEADER and BLOCK_TRAILER). In the case where there is a mask and MASK_INTERLEAVED_WITH_IMAGERY=YES, then the tile size indicated

in the leader will be < TileOffset[i+1]-TileOffset[i] since the data for the mask will follow the imagery data (see MASK_INTERLEAVED_WITH_IMAGERY=YES)

For INTERLEAVE=BAND, the above paragraph applies but the successor of tile i is not tile i+1, but tile i+nTilesPerBand.

Each tile data is immediately followed by a trailer, consisting of the repetition of the last 4 bytes of the payload of the tile data. The size of this trailer is *not* included in the TileByteCounts[] array. The purpose of this trailer is forces readers to be able to check if TIFF writers, not aware of those optimizations, have modified the TIFF file in a way that breaks the optimizations. If an optimized reader detects an inconsistency, it can then fallbacks to the regular/slower method of using TileOffsets[i] + TileByteCounts[i].

6.17.5 Examples

6.17.5.1 Example 1: Create a COG with gdalwarp

```
$ gdalwarp src1.tif src2.tif out.tif -of COG
```

6.17.5.2 Example 2: Create a Web Mercator COG with Google Maps–Compatible Tiling and JPEG Compression

```
$ gdal_translate world.tif world_webmerc_cog.tif -of COG -co TILING_
↪SCHEME=GoogleMapsCompatible -co COMPRESS=JPEG
```

6.17.5.3 Example 3: Create a blank GeoTIFF from an existing file

Use *SPARSE_OK* to create an empty file with the same georeferencing and tiling as the input, without physically writing zero-filled tiles to disk. In this example, an input of size `7640 × 8133` produces a ~4 KB file instead of ~242 MB.

Note sparse GeoTIFF files are not widely supported by non-GDAL software.

```
$ gdal raster create --like in.tif out.tif --of COG \
    --co SPARSE_OK=ON \
    --overwrite
```

6.17.6 See Also

- *GTiff -- GeoTIFF File Format* driver
- If your source dataset is an internally tiled geotiff with the desired georeferencing and compression, using cogger (possibly along with gdaladdo to create overviews) will be much faster than the COG driver.

6.18 COSAR -- TerraSAR-X Complex SAR Data Product

Driver short name

COSAR

Driver built-in by default

This driver is built-in by default

This driver provides the capability to read TerraSAR-X complex data. While most users will receive products in GeoTIFF format (representing detected radiation reflected from the targets, or geocoded data), ScanSAR products will be distributed in COSAR format.

Essentially, COSAR is an annotated binary matrix, with each sample held in 4 bytes (16 bits real, 16 bits imaginary) stored with the most significant byte first (Big Endian). Within a COSAR container there are one or more "bursts" which represent individual ScanSAR bursts. Note that if a Stripmap or Spotlight product is held in a COSAR container it is stored in a single burst.

Support for ScanSAR data is currently under way, due to the difficulties in fitting the ScanSAR "burst" identifiers into the GDAL model.

6.18.1 Driver capabilities

Supports VirtualIO

This driver supports *virtual I/O operations (/vsimem/, etc.)*

6.18.2 See Also

- DLR Document TX-GS-DD-3307 "Level 1b Product Format Specification."

6.19 CPG -- Convair PolGASP data

Driver short name

CPG

Driver built-in by default

This driver is built-in by default

NOTE: Implemented as cpgdataset.cpp.

6.19.1 Driver capabilities

Supports Georeferencing

This driver supports georeferencing

Supports VirtualIO

This driver supports *virtual I/O operations (/vsimem/, etc.)*

6.20 CPHD - Compensated Phase History Data

Driver short name

CPHD

Added in version 3.13.

GDAL can read CPHD datasets using the *RAWDataset* driver.

6.20.1 Driver capabilities

Supports VirtualIO

This driver supports *virtual I/O operations (/vsimem/, etc.)*

6.20.2 Open options

The following open options exist:

- **INCLUDE_XML=[YES/NO]:** Whether to include CPHD XML in the output, default is YES.

6.20.3 Multidimensional API support

The CPHD driver supports the *Multidimensional Raster Data Model* for reading operations.

The driver supports: - reading groups and subgroups - reading multidimensional dense arrays with a numeric data type - reading numeric or string attributes in groups and arrays

6.20.4 See Also

- CPHD v1.1.0 standard
- CPHD v1.1.0 XML schema

6.21 CTG -- USGS LULC Composite Theme Grid

Driver short name

CTG

Driver built-in by default

This driver is built-in by default

This driver can read USGS Land Use and Land Cover (LULC) grids encoded in the Character Composite Theme Grid (CTG) format. Each file is reported as a 6-band dataset of type Int32. The meaning of each band is the following one :

1. Land Use and Land Cover Code
2. Political units Code

3. Census county subdivisions and SMSA tracts Code
4. Hydrologic units Code
5. Federal land ownership Code
6. State land ownership Code

Those files are typically named grid_cell.gz, grid_cell1.gz or grid_cell2.gz on the USGS site.

- Land Use and Land Cover Digital Data (Data Users Guide 4) - PDF version from USGS
- Land Use and Land Cover Digital Data (Data Users Guide 4) - HTML version converted by Ben Discoe
- USGS LULC data at 250K and 100K

NOTE: Implemented as ctgdataset.cpp.

6.21.1 Driver capabilities

Supports Georeferencing

This driver supports georeferencing

Supports VirtualIO

This driver supports *virtual I/O operations (/vsimem/, etc.)*

6.22 DAAS (Airbus DS Intelligence Data As A Service driver)

Driver short name

DAAS

Added in version 3.0.

Build dependencies

libcurl

This driver can connect to the Airbus DS Intelligence Data As A Service API. GDAL/OGR must be built with Curl support in order for the DAAS driver to be compiled.

Orthorectified (with geotransform) and raw (with RPCs) images are supported.

Overviews are supported.

The API is not publicly available but will be released soon. Further information will be found here: https://api.oneatlas.airbus.com/

6.22.1 Driver capabilities

Supports Georeferencing

This driver supports georeferencing

6.22.2 Dataset name syntax

The nominal syntax to open a datasource is :

```
DAAS:https://example.com/path/to/image/metadata
```

A more minimal syntax can be used:

```
DAAS:
```

provided that the GET_METADATA_URL open option is filled.

6.22.3 Authentication

Access to the API requires an authentication token. There are two methods supported:

- Authentication with an API key and a client id. They must be provided respectively with the *API_KEY* open option (or *GDAL_DAAS_API_KEY* configuration option) and the *CLIENT_ID* open option (or *GDAL_DAAS_CLIENT_ID* configuration option). In that case, the driver will authenticate against the authentication endpoint to get an access token.
- Directly providing the access token with the *ACCESS_TOKEN* open option (or *GDAL_DAAS_ACCESS_TOKEN* configuration option).

In both cases, the *X_FORWARDED_USER* open option (or *GDAL_DAAS_X_FORWARDED_USER* configuration option) can be specified to fill the HTTP X-Forwarded-User header in requests sent to the DAAS service endpoint with the user from which the request originates from.

See https://api.oneatlas.airbus.com/guides/g-authentication/ for further details

6.22.4 Configuration options

Configuration options can be specified in command-line tools using the syntax `--config <NAME>=<VALUE>` or using functions such as *CPLSetConfigOption()* (C) or *gdal.config_options* (Python). The following configuration options are available :

- **GDAL_DAAS_API_KEY=value:** Equivalent of *API_KEY* open option.
- **GDAL_DAAS_CLIENT_ID=value:** Equivalent of *CLIENT_ID* open option.
- **GDAL_DAAS_ACCESS_TOKEN=value:** Equivalent of *ACCESS_TOKEN* open option.
- **GDAL_DAAS_X_FORWARDED_USER=value:** Equivalent of *X_FORWARDED_USER* open option.

6.22.5 Open options

Open options can be specified in command-line tools using the syntax `-oo <NAME>=<VALUE>` or by providing the appropriate arguments to *GDALOpenEx()* (C) or *gdal.OpenEx* (Python). The following open options are available :

- **GET_METADATA_URL=value:** URL to the GetImageMetadata endpoint. Required if not specified in the connection string.

- **API_KEY=value:** API key for authentication. If specified, must be used together with the *CLIENT_ID* option. Can be specified also through the *GDAL_DAAS_API_KEY* configuration option.
- **CLIENT_ID=value:** Client id for authentication. If specified, must be used together with the *API_KEY* option. Can be specified also through the *GDAL_DAAS_CLIENT_ID* configuration option.
- **ACCESS_TOKEN=value:** Access token. Can be specified also through the *GDAL_DAAS_ACCESS_TOKEN* configuration option. Exclusive of *API_KEY*/*CLIENT_ID*.
- **X_FORWARDED_USER=value:** User from which the request originates from. Can be specified also through the *GDAL_DAAS_X_FORWARDED_USER* configuration option.
- **BLOCK_SIZE=64-8192:** Defaults to `512`. Size of a block in pixels requested to the server.
- **PIXEL_ENCODING=[AUTO/RAW/PNG/JPEG/JPEG2000]:** Defaults to `AUTO`. Format in which pixels are queried:
  - **AUTO**: for 1, 3 or 4-band images of type Byte, resolves to PNG. Otherwise to RAW
  - **RAW**: compatible with all images. Pixels are requested in a uncompressed raw format.
  - **PNG**: compatible with 1, 3 or 4-band images of type Byte
  - **JPEG**: compatible with 1 or 3-band images of type Byte
  - **JPEG2000**: compatible with all images. Requires GDAL to be built with one of its JPEG2000-capable drivers.
- **MASKS=[YES/NO]:** Defaults to `YES`. Whether to expose mask bands.

6.23 DDS -- DirectDraw Surface

Driver short name

DDS

Build dependencies

Crunch Lib

The DirectDraw Surface file format (uses the filename extension DDS), from Microsoft, is a standard for storing data compressed with the lossy S3 Texture Compression (S3TC) algorithm. The DDS format and compression are provided by the crunch library.

Support for reading has been added in GDAL 3.1. Previous versions have write-only support.

The driver supports the following texture formats: DXT1, DXT1A, DXT3 (default), DXT5 and ETC1. You can set the texture format using the creation option FORMAT.

The driver supports the following compression quality: SUPERFAST, FAST, NORMAL (default), BETTER and UBER. You can set the compression quality using the creation option QUALITY.

More information about Crunch Lib (see below for build instructions of a working fork of that repository)

NOTE: Implemented as ddsdataset.cpp.

6.23.1 Driver capabilities

Supports CreateCopy()

This driver supports the *GDALDriver::CreateCopy()* operation

6.23.2 Build instructions

Building crunch can be a bit difficult. The *build_fixes* branch of https://github.com/rouault/crunch/ includes a CMake build system, as well as a few fixes that are not found in the upstream repository

6.23.2.1 Build crunch

Linux

```
git clone -b build_fixes https://github.com/rouault/crunch
cd crunch
mkdir build
cd build
cmake .. -DCMAKE_INSTALL_PREFIX=$HOME/install-crunch -DCMAKE_BUILD_TYPE=Release
make -j8 install
```

Windows

```
git clone -b build_fixes https://github.com/rouault/crunch
cd crunch
mkdir build
cd build
cmake .. -DCMAKE_INSTALL_PREFIX=c:\dev\install-crunch -G "Visual Studio 15 2017 Win64"
cmake --build . --config Release --target install
```

6.23.2.2 Build GDAL against crunch

Linux

```
./configure --with-dds=$HOME/install-crunch
```

Windows

In nmake.local, add the following lines:

```
CRUNCH_INC = -Ic:\dev\install-crunch\include\crunch
CRUNCH_LIB = c:\dev\install-crunch\lib\crunch.lib
```

6.24 DERIVED -- Derived subdatasets driver

Driver short name

DERIVED

Driver built-in by default

This driver is built-in by default

This driver allows accessing subdatasets derived from a given dataset. Those derived datasets have the same projection reference, geo-transform and metadata than the original dataset, but derives new pixel values using gdal pixel functions.

6.24.1 Available functions

Available derived datasets are:

- AMPLITUDE: Amplitude of pixels from input bands
- PHASE: Phase of pixels from input bands
- REAL: Real part of pixels from input bands
- IMAG: Imaginary part of pixels from input bands
- CONJ: Conjugate of pixels from input bands
- INTENSITY: Intensity (squared amplitude) of pixels from input bands
- LOGAMPLITUDE: Log10 of amplitude of pixels from input bands

Note: for non-complex data types, only LOGAMPLITUDE will be listed.

A typical use is to directly access amplitude, phase or log-amplitude of any complex dataset.

6.24.2 Accessing derived subdatasets

Derived subdatasets are stored in the DERIVED_SUBDATASETS metadata domain, and can be accessed using the following syntax:

```
DERIVED_SUBDATASET:FUNCTION:dataset_name
```

where function is one of AMPLITUDE, PHASE, REAL, IMAG, CONJ, INTENSITY, LOGAMPLITUDE. So as to ensure numerical precision, all derived subdatasets bands will have Float64 or CFloat64 precision (depending on the function used).

For instance:

```
$ gdalinfo cint_sar.tif
```

```
Driver: GTiff/GeoTIFF
Files: cint_sar.tif
Size is 5, 6
Coordinate System is `'
GCP Projection =

```

6.24.3 Listing available subdatasets

Available subdatasets are reported in the DERIVED_SUBDATASETS metadata domain. Only functions that make sense will be reported for a given dataset, which means that AMPLITUDE, PHASE, REAL, IMAG, CONJ and INTENSITY will only be reported if the dataset has at least one complex band. Nevertheless, even if not reported, those derived datasets are still reachable with the syntax presented above.

```
$ gdalinfo -mdd DERIVED_SUBDATASETS cint_sar.tif
```

```
Driver: GTiff/GeoTIFF
Files: cint_sar.tif
Size is 5, 6
Coordinate System is `'
GCP Projection =

6.25 DIMAP -- Spot DIMAP

Driver short name

DIMAP

Driver built-in by default

This driver is built-in by default

This is a read-only read for Spot DIMAP described images. To use, select the METADATA.DIM (DIMAP 1), VOL_PHR.XML (DIMAP 2) or VOL_PNEO.XML (DIMAP 2 VHR-2020) file in a product directory, or the product directory itself.

The imagery is in a distinct imagery file, often a TIFF file, but the DIMAP dataset handles accessing that file, and attaches geolocation and other metadata to the dataset from the metadata xml file.

The content of the <Spectral_Band_Info> node is reported as metadata at the level of the raster band. Note that the content of the Spectral_Band_Info of the first band is still reported as metadata of the dataset, but this should be considered as a deprecated way of getting this information.

For multi-component products, each component will be exposed in a subdataset.

NOTE: Implemented as dimapdataset.cpp.

6.25.1 Driver capabilities

Supports Georeferencing

This driver supports georeferencing

Supports VirtualIO

This driver supports *virtual I/O operations (/vsimem/, etc.)*

6.26 DOQ1 -- First Generation USGS DOQ

Driver short name

DOQ1

Driver built-in by default

This driver is built-in by default

Support for read access, including reading of an affine georeferencing transform, and capture of the projection string. This format is the old, unlabelled DOQ (Digital Ortho Quad) format from the USGS.

NOTE: Implemented as doq1dataset.cpp.

6.26.1 Driver capabilities

Supports Georeferencing

This driver supports georeferencing

Supports VirtualIO

This driver supports *virtual I/O operations (/vsimem/, etc.)*

6.27 DOQ2 -- New Labelled USGS DOQ

Driver short name

DOQ2

Driver built-in by default

This driver is built-in by default

Support for read access, including reading of an affine georeferencing transform, capture of the projection string and reading of other auxiliary fields as metadata. This format is the new, labelled DOQ (Digital Ortho Quad) format from the USGS.

This driver was implemented by Derrick J Brashear.

NOTE: Implemented as doq2dataset.cpp.

See Also: USGS DOQ Standards

6.27.1 Driver capabilities

Supports Georeferencing

This driver supports georeferencing

Supports VirtualIO

This driver supports *virtual I/O operations (/vsimem/, etc.)*

6.28 DTED -- Military Elevation Data

Driver short name

DTED

Driver built-in by default

This driver is built-in by default

GDAL supports DTED Levels 0, 1, and 2 elevation data for read access. Elevation data is returned as 16 bit signed integer. Appropriate projection and georeferencing information is also returned. A variety of header fields are returned dataset level metadata.

6.28.1 Driver capabilities

Supports CreateCopy()

This driver supports the *GDALDriver::CreateCopy()* operation

Supports Georeferencing

This driver supports georeferencing

Supports VirtualIO

This driver supports *virtual I/O operations (/vsimem/, etc.)*

6.28.1.1 Configuration options

Configuration options can be specified in command-line tools using the syntax `--config <NAME>=<VALUE>` or using functions such as *CPLSetConfigOption()* (C) or *gdal.config_options* (Python). This paragraph lists the configuration options that can be set to alter the default behavior of the DTED driver.

- **GDAL_DTED_SINGLE_BLOCK=[TRUE/FALSE]:** Defaults to `FALSE`. Determines whether to read the entire file as a single block. See *Read speed*.
- **REPORT_COMPD_CS=[TRUE/FALSE]:** Defaults to `FALSE`. Can be set to TRUE to avoid stripping the vertical CS of compound CS when reading the SRS of a file.
- **DTED_VERIFY_CHECKSUM=[YES/NO]:** Defaults to `NO`. Determine whether to issue an error/warning if the checksum written do the DTED file does not match its contents. See *Checksum Issues*.
- **DTED_APPLY_PIXEL_IS_POINT=[TRUE/FALSE]:** (GDAL >= 3.1) Defaults to `FALSE`. If `TRUE`, apply a pixel-is-point interpretation to the data when reading the geotransform.
- **DTED_ASSUME_CONFORMANT=[TRUE/FALSE]:** (GDAL >= 3.12) Defaults to `FALSE`. If `TRUE`, assume that the DTED file is conformant to the DTED standard and not in two's complement form. This will cause the DTED driver to skip the check for values less than -16000 and not change them to signed magnitude - assuming they are two's complement before the conversion.

6.28.2 Read Issues

6.28.2.1 Read speed

Elevation data in DTED files are organized per columns. This data organization doesn't fit very well with some scanline oriented algorithms and can cause slowdowns, especially for DTED Level 2 datasets. By defining *`GDAL_DTED_SINGLE_BLOCK=TRUE`*, a whole DTED dataset will be considered as a single block. The first access to the file will be slow, but further accesses will be much quicker. Only use that option if you need to do processing on a whole file.

6.28.2.2 Georeferencing Issues

The DTED specification (MIL-PRF-89020B) states that *horizontal datum shall be the World Geodetic System (WGS 84)*. The vertical datum is defined as EGM96, or EPSG:5773. However, there are still people using old data files georeferenced in WGS 72. A header field indicates the horizontal datum code, so we can detect and handle this situation.

- If the horizontal datum specified in the DTED file is WGS84, the DTED driver will report WGS 84 as SRS.
- If the horizontal datum specified in the DTED file is WGS72, the DTED driver will report WGS 72 as SRS and issue a warning.
- If the horizontal datum specified in the DTED file is neither WGS84 nor WGS72, the DTED driver will report WGS 84 as SRS and issue a warning.

6.28.2.3 Checksum Issues

The default behavior of the DTED driver is to ignore the checksum while reading data from the files. However, you may specify the environment variable `DTED_VERIFY_CHECKSUM=YES` if you want the checksums to be verified. In some cases, the checksum written in the DTED file is wrong (the data producer did a wrong job). This will be reported as a warning. If the checksum written in the DTED file and the checksum computed from the data do not match, an error will be issued.

6.28.3 Creation Issues

The DTED driver does support creating new files, but the input data must be exactly formatted as a Level 0, 1 or 2 cell. That is the size, and bounds must be appropriate for a cell.

6.28.4 See Also

- Implemented as dteddataset.cpp.

6.29 E57: ASTM E57 3D file format (image part)

Added in version 3.13.

Driver short name

E57

Driver built-in by default

but the JPEG or PNG drivers must be available.

This is a read-only driver that reads 2D images potentially included in a ASTM E57 3D file.

It does NOT read the point cloud part of such files. For that, you may use PDAL's E57 reader.

Masks are combined with the JPEG/PNG image and reported as GDAL mask bands.

If a single JPEG or PNG image is included in the file, it is directly reported. Otherwise if there are multiple images, opening the .e57 file will report several subdatasets, whose connection string is of the form `E57:"{filename.e57}":{image_name}`.

The XML descriptor contained in a E57 file can be accessed in the `xml:E57` metadata domain.

Checksums at end of E57 physical pages are not verified.

6.29.1 Driver capabilities

Supports VirtualIO

This driver supports *virtual I/O operations (/vsimem/, etc.)*

6.29.2 See Also

- ASTM Standard Specification for 3D Imaging Data Exchange, Version 1.0

6.30 ECRGTOC -- ECRG Table Of Contents (TOC.xml)

Driver short name

ECRGTOC

Driver built-in by default

This driver is built-in by default

This is a read-only reader for ECRG (Enhanced Compressed Raster Graphic) products, that uses the table of content file, TOC.xml, and exposes it as a virtual dataset whose coverage is the set of ECRG frames contained in the table of content.

The driver will report a different subdataset for each subdataset found in the TOC.xml file. Each subdataset consists of the frames of same product id, disk id, and with same scale.

Result of a gdalinfo on a TOC.xml file.

```
Subdatasets:
  SUBDATASET_1_NAME=ECRG_TOC_ENTRY:ECRG:FalconView:1_500_K:ECRG_Sample/EPF/TOC.xml
  SUBDATASET_1_DESC=Product ECRG, Disk FalconView, Scale 1:500 K
```

6.30.1 Driver capabilities

Supports Georeferencing

This driver supports georeferencing

Supports VirtualIO

This driver supports *virtual I/O operations (/vsimem/, etc.)*

6.30.2 See Also

- *NITF -- National Imagery Transmission Format (also CIB, CADRG, ECRG, HRE)*: format of the ECRG frames
- MIL-PRF-32283 : specification of ECRG products

NOTE: Implemented as ecrgtocdataset.cpp

6.31 ECW -- Enhanced Compressed Wavelets (.ecw)

Driver short name

ECW

Build dependencies

ECW SDK

GDAL supports reading and writing ECW files using the ERDAS ECW/JP2 SDK developed by Hexagon Geospatial (formerly Intergraph, ERDAS, ERMapper). Support is optional and requires linking in the libraries available from the ECW/JP2 SDK Download page.

6.31.1 Driver capabilities

Supports CreateCopy()

This driver supports the *GDALDriver::CreateCopy()* operation

Supports Create()

This driver supports the *GDALDriver::Create()* operation

Supports Georeferencing

This driver supports georeferencing

Supports VirtualIO

This driver supports *virtual I/O operations (/vsimem/, etc.)*

6.31.2 Licensing

The ERDAS ECW/JP2 SDK v5.x is available under multiple license types. For Desktop usage, decoding any sized ECW/JP2 image is made available free of charge. To compress, deploy on a Server platform, or decode unlimited sized files on Mobile platforms a license must be purchased from Hexagon Geospatial.

6.31.3 History

- v3.x - Last release, 2006
- v4.x - Last release, 2012
- v5.x - Active development, 2013 - current

6.31.4 Creation Options

The ERDAS ECW/JP2 v4.x and v5.x SDK is only free for image decompression. To compress images it is necessary to build with the read/write SDK and to provide an OEM licensing key at runtime which may be purchased from ERDAS.

For those still using the ECW 3.3 SDK, images less than 500MB may be compressed for free, while larger images require licensing from ERDAS. See the licensing agreement and the LARGE_OK option.

Files to be compressed into ECW format must also be at least 128x128. ECW currently only supports 8 bits per channel for ECW Version 2 files. ECW Version 3 files supports 16 bits per channel (as Uint16 data type). Please see Creation options to enable ECW V3 files writing

When writing coordinate system information to ECW files, many less common coordinate systems are not mapped properly. If you know the ECW name for the coordinate system you can force it to be set at creation time with the PROJ and DATUM creation options.

ECW format does not support creation of overviews since the ECW format is already considered to be optimized for "arbitrary overviews".

6.31.5 Creation Options:

Creation options can be specified in command-line tools using the syntax `-co <NAME>=<VALUE>` or by providing the appropriate arguments to *GDALCreate()* (C) or *Driver.Create* (Python). The following creation options are supported:

- **LARGE_OK=[YES/NO]:** *(v3.x SDK only)* Allow compressing files larger than 500MB in accordance with EULA terms. Deprecated since v4.x and replaced by *ECW_ENCODE_KEY* & *ECW_ENCODE_COMPANY*.
- **ECW_ENCODE_KEY=value:** *(v4.x SDK or higher)* Provide the OEM encoding key to unlock encoding capability up to the licensed gigapixel limit. The key is approximately 129 hex digits long. The Company and Key must match and must be re-generated with each minor release of the SDK. It may also be provided globally as a configuration option.
- **ECW_ENCODE_COMPANY=value:** *(v4.x SDK or higher)* Provide the name of the company in the issued OEM key (see *ECW_ENCODE_KEY*). The Company and Key must match and must be re-generated with each minor release of the SDK. It may also be provided globally as a configuration option.
- **TARGET=value:** Set the target size reduction as a percentage of the original. If not provided defaults to 90% for greyscale images, and 95% for RGB images.
- **PROJ=value:** Name of the ECW projection string to use. Common examples are NUTM11, or GEODETIC.
- **DATUM=value:** Name of the ECW datum string to use. Common examples are WGS84 or NAD83.
- **UNITS=[METERS/FEET]:** Defaults to `METERS`. Name of the ECW projection units to use : METERS (default) or FEET (us-foot).
- **ECW_FORMAT_VERSION=[2/3]:** Defaults to `2`. When building with the ECW 5.x SDK this option can be set to allow ECW Version 3 files to be created. Default, 2 to retain widest compatibility.

6.31.6 Configuration Options

Configuration options can be specified in command-line tools using the syntax `--config <NAME>=<VALUE>` or using functions such as *CPLSetConfigOption()* (C) or *gdal.config_options* (Python). The ERDAS ECW SDK supports a variety of configuration options to control various features. See the ECW SDK documentation for full details on the meaning of these options.

- **ECW_CACHE_MAXMEM=<bytes>:** maximum bytes of RAM used for in-memory caching. If not set, up to one quarter of physical RAM will be used by the SDK for in-memory caching.
- **ECWP_CACHE_LOCATION=<path>:** Path to a directory to use for caching ECWP results. If unset ECWP caching will not be enabled.
- **ECWP_CACHE_SIZE_MB=<megabytes>:** The maximum number of megabytes of space in the *ECWP_CACHE_LOCATION* to be used for caching ECWP results.
- **ECWP_BLOCKING_TIME_MS=<milliseconds>:** Defaults to `10000`. time an ecwp:// blocking read will wait before returning.
- **ECWP_REFRESH_TIME_MS=<milliseconds>:** Defaults to `10000`. time delay between blocks arriving and the next refresh callback. For the purposes of GDAL this is the amount of time the driver will wait for more data on an ecwp connection for which the final result has not yet been returned. If set small then RasterIO() requests will often produce low resolution results.
- **ECW_TEXTURE_DITHER=[TRUE/FALSE]:** Defaults to `TRUE`. This may be set to FALSE to disable dithering when decompressing ECW files.
- **ECW_FORCE_FILE_REOPEN=[TRUE/FALSE]:** Defaults to `FALSE`. This may be set to TRUE to force open a file handle for each file for each connection made.
- **ECW_CACHE_MAXOPEN=<integer>:** The maximum number of files to keep open for ECW file handle caching. Defaults to unlimited.

- **ECW_RESILIENT_DECODING=[TRUE/FALSE]:** Defaults to TRUE. Controls whether the reader should be forgiving of errors in a file, trying to return as much data as is available. If set to FALSE an invalid file will result in an error.

The GDAL-specific options:

- **ECW_ALWAYS_UPWARD=[TRUE/FALSE]:** Defaults to TRUE. If TRUE, the driver sets negative Y-resolution and assumes an image always has the "Upward" orientation (Y coordinates increase upward). This may be set to FALSE to let the driver rely on the actual image orientation, using Y-resolution value (sign) of an image, to allow correct processing of rare images with "Downward" orientation (Y coordinates increase "Downward" and Y-resolution is positive). Defaults to TRUE.

6.31.6.1 ECW Version 3 Files

ECW 5.x SDK introduces a new file format version which,

1. Storage of data statistics, histograms, metadata, RPC information within the file header
2. Support for UInt16 data type
3. Ability to update regions within an existing ECW v3 file
4. Introduces other space saving optimizations

Note: This version is not backward compatible and will fail to decode in v3.x or v4.x ECW/JP2 SDK's. The File VERSION Metadata will advertise whether the file is ECW v2 or ECW v3.

6.31.6.2 ECWP

In addition to local files, this driver also supports access to streaming network imagery services using the proprietary "ECWP" protocol from the ERDAS APOLLO product. Use the full ecwp:// prefixed dataset url as input. When built with ECW/JP2 SDK v4.1 or newer it is also possible to take advantage of rfc-24 for asynchronous / progressive streaming access to ECWP services.

6.31.6.3 Metadata / Georeferencing

The PROJ, DATUM and UNITS found in the ECW header are reported in the ECW metadata domain. They can also be set with the SetMetadataItem() method, in order to update the header information of an existing ECW file, opened in update mode, without modifying the imagery.

The geotransform and projection can also be modified with the SetGeoTransform() and SetProjection() methods. If the projection is set with SetProjection() and the PROJ, DATUM or UNITS with SetMetadataItem(), the later values will override the values built from the projection string.

All those can for example be modified with the -a_ullr, -a_srs or -mo switches of the *gdal_edit* utility.

For example:

```
gdal_edit.py -mo DATUM=WGS84 -mo PROJ=GEODETIC -a_ullr 7 47 8 46 test.ecw

gdal_edit.py -a_srs EPSG:3068 -a_ullr 20800 22000 24000 19600 test.ecw
```

6.31.6.4 File Metadata Keys:

- FILE_METADATA_ACQUISITION_DATE
- FILE_METADATA_ACQUISITION_SENSOR_NAME
- FILE_METADATA_ADDRESS
- FILE_METADATA_AUTHOR

- FILE_METADATA_CLASSIFICATION
- FILE_METADATA_COMPANY - should be set to ECW_ENCODE_COMPANY
- FILE_METADATA_COMPRESSION_SOFTWARE - updated during recompression
- FILE_METADATA_COPYRIGHT
- FILE_METADATA_EMAIL
- FILE_METADATA_TELEPHONE
- CLOCKWISE_ROTATION_DEG
- COLORSPACE
- COMPRESSION_DATE
- COMPRESSION_RATE_ACTUAL
- COMPRESSION_RATE_TARGET. This is the percentage of the target compressed file size divided by the uncompressed file size. This is equal to 100 / (100 - TARGET) where TARGET is the value of the TARGET creation option used at file creation, so a COMPRESSION_RATE_TARGET=1 is equivalent to a TARGET=0 (ie no compression), COMPRESSION_RATE_TARGET=5 is equivalent to TARGET=80 (ie dividing uncompressed file size by 5), etc...
- VERSION

6.31.7 Standalone plugin compilation

Added in version 3.10.

While this driver may be built as part of a whole GDAL build, either in libgdal itself, or as a plugin, it is also possible to only build this driver as a plugin, against an already built libgdal.

The version of the GDAL sources used to build the driver must match the version of the libgdal it is built against.

For example, from a "build_georaster" directory under the root of the GDAL source tree:

```
cmake -S ../frmts/ecw -DCMAKE_PREFIX_PATH=/path/to/GDAL_installation_prefix -DECW_ROOT=/
↪path/to/ecw_sdk_root
cmake --build .
```

Note that such a plugin, when used against a libgdal not aware of it, will be systematically loaded at GDAL driver initialization time, and will not benefit from *deferred plugin loading capabilities <rfc-96>*. For that, libgdal itself must be built with the CMake variable GDAL_REGISTER_DRIVER_ECW_FOR_LATER_PLUGIN=ON set.

6.32 EEDAI - Google Earth Engine Data API Image

Driver short name

EEDAI

Build dependencies

libcurl

The driver supports read-only operations to access image content, using Google Earth Engine REST API.

6.32.1 Driver capabilities

Supports Georeferencing

This driver supports georeferencing

6.32.2 Dataset name syntax

The minimal syntax to open a datasource is :

```
EEDAI:[asset][:band_names]
```

where asset is something like projects/earthengine-public/assets/COPERNICUS/S2/20170430T190351_20170430T190351_T10SEG, and band_names a comma separated list of band names (typically indicated by subdatasets on the main image)

6.32.3 Open options

Open options can be specified in command-line tools using the syntax `-oo <NAME>=<VALUE>` or by providing the appropriate arguments to *`GDALOpenEx()`* (C) or *`gdal.OpenEx`* (Python). The following open options are available :

- **ASSET=<string>:** To specify the asset if not specified in the connection string.
- **BANDS=value:** Comma separated list of band names.
- **PIXEL_ENCODING=[AUTO/PNG/JPEG/AUTO_JPEG_PNG/GEO_TIFF/NPY]:** Format in which to request pixels.
- **BLOCK_SIZE=<integer>:** Defaults to `256`. Size of a GDAL block, which is the minimum unit to query pixels.
- **VSI_PATH_FOR_AUTH=value:** (GDAL >= 3.10) /vsigs/... path onto which a GOOGLE_APPLICATION_CREDENTIALS path specific option is set

6.32.4 Authentication methods

The following authentication methods can be used:

- Authentication Bearer header passed through the *`EEDA_BEARER`* or *`EEDA_BEARER_FILE`* configuration options.
- Service account private key file, through the *`GOOGLE_APPLICATION_CREDENTIALS`* configuration option, or set as a path-specific option whose value is set in the VSI_PATH_FOR_AUTH open option.

- OAuth2 Service Account authentication through the *EEDA_PRIVATE_KEY*/ *EEDA_PRIVATE_KEY_FILE* + *EEDA_CLIENT_EMAIL* configuration options.
- Finally if none of the above method succeeds, the code will check if the current machine is a Google Compute Engine instance, and if so will use the permissions associated to it (using the default service account associated with the VM). To force a machine to be detected as a GCE instance (for example for code running in a container with no access to the boot logs), you can set *CPL_MACHINE_IS_GCE=YES*.

6.32.5 Configuration options

Configuration options can be specified in command-line tools using the syntax `--config <NAME>=<VALUE>` or using functions such as *CPLSetConfigOption()* (C) or *gdal.config_options* (Python). The following configuration options are available :

- **EEDA_BEARER=value:** Authentication Bearer value to pass to the API. This option is only useful when the token is computed by external code. The bearer validity is typically one hour from the time where it as been requested.
- **EEDA_BEARER_FILE=<filename>:** Similar to *EEDA_BEARER* option, except than instead of passing the value directly, it is the filename where the value should be read.
- **GOOGLE_APPLICATION_CREDENTIALS=<file.json>:** Service account private key file that contains a private key and client email
- **EEDA_PRIVATE_KEY=value:** RSA private key encoded as a PKCS#8 PEM file, with its header and footer. Used together with *EEDA_CLIENT_EMAIL* to use OAuth2 Service Account authentication. Requires GDAL to be built against libcrypto++ or libssl.
- **EEDA_PRIVATE_KEY_FILE=<filename>:** Similar to *EEDA_PRIVATE_KEY* option, except than instead of passing the value directly, it is the filename where the key should be read.
- **EEDA_CLIENT_EMAIL=value:** email to be specified together with *EEDA_PRIVATE_KEY*/*EEDA_PRIVATE_KEY_FILE* to use OAuth2 Service Account authentication.
- **CPL_MACHINE_IS_GCE=[YES/NO]:** Defaults to `NO`. If `YES`, forces GDAL to consider the current machine to be a a Google Compute Engine instance. May be needed for code running in a container with no access to the boot logs.

6.32.6 Overviews

The driver expose overviews, following a logic of decreasing power of 2 factors, until both dimensions of the smallest overview are lower than 256 pixels.

6.32.7 Subdatasets

When all bands don't have the same georeferencing, resolution, CRS or image dimensions, the driver will expose subdatasets. Each subdataset groups together bands of the same dimension, extent, resolution and CRS.

6.32.8 Metadata

The driver will expose metadata reported in "properties" as dataset-level or band-level metadata.

6.32.9 Pixel encoding

By default (*PIXEL_ENCODING=AUTO*), the driver will request pixels in a format compatible with the number and data types of the bands. The PNG, JPEG and AUTO_JPEG_PNG can only be used with bands of type Byte.

6.32.9.1 Examples

Get metadata on an image:

```
gdalinfo "EEDAI:" -oo ASSET=projects/earthengine-public/assets/COPERNICUS/S2/
↪20170430T190351_20170430T190351_T10SEG --config EEDA_CLIENT_EMAIL "my@email" --config␣
↪EEDA_PRIVATE_KEY_FILE my.pem
```

or

```
gdalinfo "EEDAI:projects/earthengine-public/assets/COPERNICUS/S2/20170430T190351_
↪20170430T190351_T10SEG" --config EEDA_CLIENT_EMAIL "my@email" --config EEDA_PRIVATE_
↪KEY_FILE my.pem
```

6.33 EHdr -- ESRI .hdr Labelled

Driver short name

EHdr

Driver built-in by default

This driver is built-in by default

GDAL supports reading and writing the ESRI .hdr labeling format, often referred to as ESRI BIL format. Eight, sixteen and thirty-two bit integer raster data types are supported as well as 32 bit floating point. Coordinate systems (from a .prj file), and georeferencing are supported. Unrecognized options in the .hdr file are ignored. To open a dataset select the file with the image file (often with the extension .bil). If present .clr color table files are read, but not written. If present, image.rep file will be read to extract the projection system of SpatioCarte Defense 1.0 raster products.

This driver does not always do well differentiating between floating point and integer data. The GDAL extension to the .hdr format to differentiate is to add a field named PIXELTYPE with values of either FLOAT, SIGNEDINT or UNSIGNEDINT. In combination with the NBITS field it is possible to described all variations of pixel types.

eg.

```
ncols 1375
nrows 649
cellsize 0.050401
xllcorner -130.128639
yllcorner 20.166799
nodata_value 9999.000000
nbits 32
pixeltype float
byteorder msbfirst
```

This driver may be sufficient to read GTOPO30 data.

NOTE: Implemented as ehdrdataset.cpp.

6.33.1 Driver capabilities

Supports CreateCopy()

This driver supports the *GDALDriver::CreateCopy()* operation

Supports Create()

This driver supports the *GDALDriver::Create()* operation

Supports Georeferencing

This driver supports georeferencing

Supports VirtualIO

This driver supports *virtual I/O operations (/vsimem/, etc.)*

6.33.2 See Also

- GTOPO30 Documentation
- SpatioCarte Defense 1.0 specification (in French)
- *SRTMHGT Driver*

6.34 EIR -- Erdas Imagine Raw

Driver short name

EIR

Driver built-in by default

This driver is built-in by default

GDAL supports the Erdas Imagine Raw format for read access including 1, 2, 4, 8, 16 and 32bit unsigned integers, 16 and 32bit signed integers and 32 and 64bit complex floating point. Georeferencing is supported.

To open a dataset select the file with the header information. The driver finds the image file from the header information. Erdas documents call the header file the "raw" file and it may have the extension .raw while the image file that contains the actual raw data may have the extension .bl.

NOTE: Implemented as eirdataset.cpp.

6.34.1 Driver capabilities

Supports Georeferencing

This driver supports georeferencing

Supports VirtualIO

This driver supports *virtual I/O operations (/vsimem/, etc.)*

6.35 ENVI -- ENVI .hdr Labelled Raster

Driver short name

ENVI

Driver built-in by default

This driver is built-in by default

GDAL supports some variations of raw raster files with associated ENVI style .hdr files describing the format. To select an existing ENVI raster file select the binary file containing the data (as opposed to the .hdr file), and GDAL will find the .hdr file by replacing the dataset extension with .hdr.

GDAL should support reading bil, bip and bsq interleaved formats, and most pixel types are supported, including 8bit unsigned, 16 and 32bit signed and unsigned integers, 32bit and 64 bit floating point, and 32bit and 64bit complex floating point. There is limited support for recognising map_info keywords with the coordinate system and georeferencing. In particular, UTM and State Plane should work.

All ENVI header fields are stored in the ENVI metadata domain, and all of these can then be written out to the header file.

Creation Options:

- **INTERLEAVE=[BSQ/BIP/BIL]:** Force the generation specified type of interleaving. **BSQ** -- band sequential (default), **BIP** --- data interleaved by pixel, **BIL** -- data interleaved by line. Starting with GDAL 3.5, when copying from a source dataset with multiple bands which advertises a INTERLEAVE metadata item, if the INTERLEAVE creation option is not specified, the source dataset INTERLEAVE will be automatically taken into account. See *Multiband pixel organization (INTERLEAVE metadata item)* for more details.
- **SUFFIX=[REPLACE/ADD]:** Force adding ".hdr" suffix to supplied filename, e.g. if user selects "file.bin" name for output dataset, "file.bin.hdr" header file will be created. By default header file suffix replaces the binary file suffix, e.g. for "file.bin" name "file.hdr" header file will be created.

NOTE: Implemented as envidataset.cpp.

6.35.1 Driver capabilities

Supports CreateCopy()

This driver supports the *GDALDriver::CreateCopy()* operation

Supports Create()

This driver supports the *GDALDriver::Create()* operation

Supports Georeferencing

This driver supports georeferencing

Supports VirtualIO

This driver supports *virtual I/O operations (/vsimem/, etc.)*

6.36 ESAT -- Envisat Image Product

Driver short name

ESAT

Driver built-in by default

This driver is built-in by default

GDAL supports the Envisat product format for read access. All sample types are supported. Files with two matching measurement datasets (MDS) are represented as having two bands. Currently all ASAR Level 1 and above products, and some MERIS and AATSR products are supported.

The control points of the GEOLOCATION GRID ADS dataset are read if available, generally giving a good coverage of the dataset. The GCPs are in WGS84.

Virtually all key/value pairs from the MPH and SPH (primary and secondary headers) are copied through as dataset level metadata.

ASAR and MERIS parameters contained in the ADS and GADS records (excluded geolocation ones) can be retrieved as key/value pairs using the "RECORDS" metadata domain.

NOTE: Implemented as envisatdataset.cpp.

See Also: Envisat at ESA.

6.36.1 Driver capabilities

Supports VirtualIO

This driver supports *virtual I/O operations (/vsimem/, etc.)*

6.37 ESRIC -- Esri Compact Cache

Driver short name

ESRIC

Driver built-in by default

This driver is built-in by default

Read Esri Compact Cache V2 as a single raster

6.37.1 Driver capabilities

Supports Georeferencing

This driver supports georeferencing

Supports VirtualIO

This driver supports *virtual I/O operations (/vsimem/, etc.)*

6.37.2 Esri Compact Cache V2

A reader for Esri Compact Cache V2. The cache is stored in multiple files located in a specific folder structure. From the point of view of this driver the raster is represented by the file named conf.xml, which resides in the root folder of the cache. The exact content of this XML file is not fully documented by Esri, and is subject to change. This driver uses only a few of the XML fields, as necessary to read the raster.

6.37.3 Esri Tile Package (.tpkx)

Starting from GDAL 3.8, the driver supports reading the Esri Tile Package Specification. A tile package is a compressed file with ".tpkx" extension. It has a simplified structure, containing image tiles stored in Compact Cache V2 storage format and tiling scheme and other metadata stored in a JSON file.

Note

Tile packages with ".tpk" extension, use compact storage V1 format for cache tiles. The spec for this package type is not available and it is not supported by GDAL.

6.37.3.1 Usage examples

If the /path/Layers contains an Esri Compact Cache in V2 format in the normal Web Mercator tile grid, this command will copy the level 2 content into a TIF file.

```
gdal_translate -outsize 1024 1024 path/Layers/conf.xml output.tif
```

To convert a .tpkx file to a GeoTIFF:

```
gdal_translate -outsize 1024 1024 /path/to/my.tpkx output.tif
```

6.37.3.2 Features and Limitations

- Only V2 Compact cache is supported. This format is identified by the value **esriMapCacheStorageModeCompactV2** in the **CacheInfo.TileCacheInfo.StorageFormat** element of the conf.xml file. Other legacy Esri cache formats are not supported.
- Only caches with tiles of 256 by 256 pixels are supported. These are stored as the values of the **CacheInfo.TileCacheInfo.TileRows** and **CacheInfo.TileCacheInfo.TileCols** elements.
- Tiles in the cache can be in different formats, including JPEG and PNG. The most common are 8 bit color or grayscale JPEG and color PNG with or without opacity. These caches will have the value **JPEG**, **PNG** or **MIXED** in the **CacheInfo.TileImageInfo.CacheTileFormat** element. Other tile formats, such as **PNG8** are not supported. The raster will be promoted to RGB or RGBA by this driver, even if the source is grayscale.
- Only caches with 128 by 128 tiles in a bundle file are supported. This value, the linear number of tiles in a bundle, is contained in the **CacheInfo.CacheStorageInfo.PacketSize** element.
- The spatial reference is obtained from the **CacheInfo.TileCacheInfo.SpatialReference.WKT** field. If this field is not present, the default value of EPSG:4326 is assumed.
- As defined in the standard conf.xml file, the cache tile grid has an origin location, stored in the **CacheInfo.TileCacheInfo.TileOrigin** element, which has X and Y components. The cache size is not explicitly defined. The ESRIC format driver will assume a symmetric area around the 0,0 coordinates, in the reference system coordinates. This is true for the standard Web Mercator and GCS reference systems. If this assumption is not valid, the conf.xml file can be modified, adding a non-standard **CacheInfo.TileCacheInfo.TileEnd** element with the appropriate values for the X and Y components, similar to the **TileOrigin**. Note that the grid origin and size is different from the raster data extent. For example, it is common to generate a cache in the standard Web Mercator tile grid, which is defined for the whole Earth, even if data is only available for a small region of the globe.
- A bundled cache has multiple resolution levels, encoded in a series of **CacheInfo.TileCacheInfo.LODInfos.LODInfo** nodes. The **LODInfo** XML nodes are identified by the **LevelID** value, which have to be successive, starting with 0 for the level with the largest value for the **Resolution** and increasing towards the **LODInfo** node with smallest **Resolution** value. The level convention is similar to other Level, Row and Column tile addressing schemes used in WMTS for example. While common, it is not a requirement to have the resolutions of two successive levels differ by a factor of two. Each cache level will be read as an overview, at the appropriate resolution. The resolution values are in spatial reference distance units per pixel.
- Many caches are built level by level from different sources, similar to many web map tile protocols supported by the GDAL WMS driver. This means that the content of a specific level might be from a different source than an adjacent one, or content for a specific level can be missing altogether. This driver will return opaque black when reading areas which do not have tiles in the cache at a given resolution level, even if data does exist at other levels at the same location.
- Starting from GDAL 3.8, the driver can automatically expand the paletted images to RGBA. The same cache may contain tiles with different color representations.

- A cache can exceed the maximum size supported by GDAL, which is INT32_MAX, in either dimension. By default, the driver will return an error when opening such caches unless the following open option is specified: `IGNORE_OVERSIZED_LODS=YES`.

6.37.4 Open options

Open options can be specified in command-line tools using the syntax `-oo <NAME>=<VALUE>` or by providing the appropriate arguments to *`GDALOpenEx()`* (C) or *`gdal.OpenEx`* (Python). The following open options are available:

- **EXTENT_SOURCE=[FULL_EXTENT/INITIAL_EXTENT/TILING_SCHEME]:** (GDAL >= 3.9.1) Defaults to `FULL_EXTENT`. Which source should be used for the extent of Esri Tile Package (.tpkx) datasets. By default, or if specifying `FULL_EXTENT`, the "fullExtent" element of the root.json file will be selected, which normally covers all tiles with data. `INITIAL_EXTENT` can be specified to use the default initial extent described in the "initialExtent" element of the root.json file. `TILING_SCHEME` will return the extent of the whole tiling scheme, which is typically world coverage.
- **IGNORE_OVERSIZED_LODS=[YES/NO]:** (GDAL >= 3.13) Defaults to `NO`. Whether to ignore LODs whose computed raster size exceeds the maximum size supported by GDAL (INT32_MAX). By default, an error will be returned when attempting to open such datasets. When set to `YES`, such LODs are ignored.

6.37.5 See Also

- Implemented as esric_dataset.cpp.

6.38 ERS -- ERMapper .ERS

Driver short name

ERS

Driver built-in by default

This driver is built-in by default

GDAL supports reading and writing raster files with .ers header files, with some limitations. The .ers ascii format is used by ERMapper for labeling raw data files, as well as for providing extended metadata, and georeferencing for some other file formats. The .ERS format, or variants are also used to hold descriptions of ERMapper algorithms, but these are not supported by GDAL.

The PROJ, DATUM and UNITS values found in the ERS header are reported in the ERS metadata domain.

6.38.1 Driver capabilities

Supports CreateCopy()

This driver supports the *`GDALDriver::CreateCopy()`* operation

Supports Create()

This driver supports the *`GDALDriver::Create()`* operation

Supports Georeferencing

This driver supports georeferencing

Supports VirtualIO

This driver supports *virtual I/O operations (/vsimem/, etc.)*

6.38.2 Creation Options

Creation options can be specified in command-line tools using the syntax `-co <NAME>=<VALUE>` or by providing the appropriate arguments to *`GDALCreate()`* (C) or *`Driver.Create`* (Python). The following creation options are supported:

- **PIXELTYPE=value:** By setting this to SIGNEDBYTE, a new Byte file can be forced to be written as signed byte. Starting with GDAL 3.7, this option is deprecated and Int8 should rather be used.
- **PROJ=value:** Name of the ERS projection string to use. Common examples are NUTM11, or GEODETIC. If defined, this will override the value computed by SetProjection() or SetGCPs().
- **DATUM=value:** Name of the ERS datum string to use. Common examples are WGS84 or NAD83. If defined, this will override the value computed by SetProjection() or SetGCPs().
- **UNITS=[METERS/FEET]:** Defaults to `METERS`. Name of the ERS projection units to use : METERS (default) or FEET (us-foot). If defined, this will override the value computed by SetProjection() or SetGCPs().

6.38.3 See Also

- Implemented as ersdataset.cpp.

6.39 EXR -- Extended Dynamic Range Image File Format

Added in version 3.1.

Driver short name

EXR

Build dependencies

libopenexr

OpenEXR is a high dynamic range raster file format. The driver supports reading and writing images in that format.

Georeferencing is written as a WKT CRS string and a 3x3 geotransform matrix in EXR header metadata.

"Deep images" are not supported.

6.39.1 Creation Options

Creation options can be specified in command-line tools using the syntax `-co <NAME>=<VALUE>` or by providing the appropriate arguments to *GDALCreate()* (C) or *Driver.Create* (Python). The following creation options are supported:

- **COMPRESS=[NONE/RLE/ZIPS/ZIP/PIZ/PXR24/B44/B44A/DWAA/DWAB]:** Defaults to `ZIP`. Compression method. Details on the format Wikipedia page
- **PIXEL_TYPE=[HALF/FLOAT/UINT]:** Pixel type used for encoding.
  - `HALF` corresponds to a IEEE-754 16-bit floating point value.
  - `FLOAT` corresponds to a IEEE-754 32-bit floating point value.
  - `UINT` corresponds to a 32-bit unsigned integer value.

  If not specified, the following GDAL data types will be mapped as following:
  - `Byte` ==> HALF
  - `Int16` ==> HALF (potentially lossy)
  - `UInt16` ==> HALF (potentially lossy)
  - `Int32` ==> FLOAT (potentially lossy)
  - `UInt32` ==> UINT
  - `Float32` ==> FLOAT
  - `Float64` ==> FLOAT (generally lossy)
- **TILED=[YES/NO]:** Defaults to `NO`. By default tiled files will be created, unless this option is set to NO. In Create() mode, setting TILED=NO is not possible.
- **BLOCKXSIZE=<integer>:** Defaults to `256`. Sets tile width.
- **BLOCKYSIZE=<integer>:** Defaults to `256`. Sets tile height.
- **OVERVIEWS=[YES/NO]:** Defaults to `NO`. Whether to create overviews. Only compatible with CreateCopy() mode.
- **OVERVIEW_RESAMPLING=[NEAR/AVERAGE/CUBIC/...]:** Defaults to `CUBIC`. Resampling method to use for overview creation.
- **PREVIEW=[YES/NO]:** Defaults to `NO`. Whether to create a preview. Only compatible with CreateCopy() mode, and with RGB(A) data of type Byte.
- **AUTO_RESCALE=[YES/NO]:** Whether to rescale Byte RGB(A) values from 0-255 to the 0-1 range usually used in EXR ecosystem.
- **DWA_COMPRESSION_LEVEL=<integer>:** DWA compression level. The higher, the more compressed the image will be (and the more artifacts). Defaults to 45 for OpenEXR 2.4

6.39.2 Driver capabilities

Supports CreateCopy()

This driver supports the *GDALDriver::CreateCopy()* operation

Supports Create()

With the caveat, that it is only for tiled data, and each tile must be written at most once, and written tiles cannot be read back before dataset closing.

Supports Georeferencing

This driver supports georeferencing

Supports VirtualIO

This driver supports *virtual I/O operations (/vsimem/, etc.)*

6.40 FAST -- EOSAT FAST Format

Driver short name

FAST

Driver built-in by default

This driver is built-in by default

Supported reading from FAST-L7A format (Landsat TM data) and EOSAT Fast Format Rev. C (IRS-1C/1D data). If you want to read other datasets in this format (SPOT), write to me (Andrey Kiselev, dron@ak4719.spb.edu). You should share data samples with me.

Datasets in FAST format represented by several files: one or more administrative headers and one or more files with actual image data in raw format. Administrative files contains different information about scene parameters including filenames of images. You can read files with administrative headers with any text viewer/editor, it is just plain ASCII text.

This driver wants administrative file for input. Filenames of images will be extracted and data will be imported, every file will be interpreted as band.

6.40.1 Driver capabilities

Supports Georeferencing

This driver supports georeferencing

Supports VirtualIO

This driver supports *virtual I/O operations (/vsimem/, etc.)*

6.40.2 Data

6.40.2.1 FAST-L7A

FAST-L7A consists form several files: big ones with image data and three small files with administrative information. You should give to driver one of the administrative files:

- L7fppprrr_rrrYYYYMMDD_HPN.FST: panchromatic band header file with 1 band
- L7fppprrr_rrrYYYYMMDD_HRF.FST: VNIR/ SWIR bands header file with 6 bands
- L7fppprrr_rrrYYYYMMDD_HTM.FST: thermal bands header file with 2 bands

All raw images corresponded to their administrative files will be imported as GDAL bands.

From the `` Level 1 Product Output Files Data Format Control Book'':

```
The file naming convention for the FAST-L7A product files is L7fppprrr_rrrYYYYMMDD_AAA.
FST where L7 = Landsat 7 mission f = ETM+ format (1 or 2) (data not pertaining to a
specific format defaults to 1) ppp = starting path of the product rrr_rrr = starting and
ending rows of the product YYYYMMDD = acquisition date of the image AAA = file type:  HPN
= panchromatic band header file HRF = VNIR/ SWIR bands header file HTM = thermal bands
header file B10 = band 1 B20 = band 2 B30 = band 3 B40 = band 4 B50 = band 5 B61 = band
6L B62 = band 6H B70 = band 7 B80 = band 8 FST = FAST file extension
```

So you should give to driver one of the `L7fppprrr_rrrYYYYMMDD_HPN.FST`, `L7fppprrr_rrrYYYYMMDD_HRF.FST` or `L7fppprrr_rrrYYYYMMDD_HTM.FST` files.

6.40.2.2 IRS-1C/1D

Fast Format REV. C does not contain band filenames in administrative header. So we should guess band filenames, because different data distributors name their files differently. Several naming schemes hardcoded in GDAL's FAST driver. These are:

```
<header>.<ext> <header>.1.<ext> <header>.2.<ext> ...
```

or

```
<header>.<ext> band1.<ext> band2.<ext> ...
```

or

```
<header>.<ext> band1.dat band2.dat ...
```

or

```
<header>.<ext> imagery1.<ext> imagery2.<ext> ...
```

or

```
<header>.<ext> imagery1.dat imagery2.dat ...
```

in lower or upper case. Header file could be named arbitrarily. This should cover majority of distributors fantasy in naming files. But if you out of luck and your datasets named differently you should rename them manually before importing data with GDAL.

GDAL also supports the logic for naming band files for datasets produced by Euromap GmbH for IRS-1C/IRS-1D PAN, LISS3 and WIFS sensors. Their filename logic is explained in the Euromap Naming Conventions document.

6.40.3 Georeference

All USGS projections should be supported (namely UTM, LCC, PS, PC, TM, OM, SOM). Contact me if you have troubles with proper projection extraction.

6.40.4 Metadata

Calibration coefficients for each band reported as metadata items.

- **ACQUISITION_DATE**: First scene acquisition date in yyyyddmm format.
- **SATELLITE**: First scene satellite name.
- **SENSOR**: First scene sensor name.
- **BIASn**: Bias value for the channel **n**.
- **GAINn**: Gain value for the channel **n**.

EOSAT Fast Format REV. C description available from http://www.euromap.de/docs/doc_001.html

6.41 FITS -- Flexible Image Transport System

Driver short name

FITS

Build dependencies

libcfitsio

FITS is a format used mainly by astronomers, but it is a relatively simple format that supports arbitrary image types and multi-spectral images, and so has found its way into GDAL. FITS support is implemented in terms of the standard CFITSIO library, which you must have on your system in order for FITS support to be enabled (see *notes on CFITSIO linking*). Both reading and writing of FITS files is supported.

Starting from version 3.0 georeferencing system support is implemented via the conversion of WCS (World Coordinate System) keywords. Only Latitude - Longitude systems (see the FITS standard document) have been implemented, those for which remote sensing processing is commonly used. As 3D Datum information is missing in FITS/WCS standard, Radii and target bodies are translated using the planetary extension proposed here.

Non-standard header keywords that are present in the FITS file will be copied to the dataset's metadata when the file is opened, for access via GDAL methods. Similarly, non-standard header keywords that the user defines in the dataset's metadata will be written to the FITS file when the GDAL handle is closed.

Note to those familiar with the CFITSIO library: The automatic rescaling of data values, triggered by the presence of the BSCALE and BZERO header keywords in a FITS file, is disabled in GDAL < v3.0. Those header keywords are accessible and updatable via dataset metadata, in the same was as any other header keywords, but they do not affect reading/writing of data values from/to the file. Starting from version 3.0 BZERO and BSCALE

keywords are managed via standard *GDALRasterBand::GetOffset()* / *GDALRasterBand::SetOffset()* and *GDALRasterBand::GetScale()* / *GDALRasterBand::SetScale()* GDAL functions and no more referred as metadata.

6.41.1 Multiple image support

Starting with GDAL 3.2, Multi-Extension FITS (MEF) files that contain one or more extensions following the primary HDU are supported. When more than 2 image HDUs are found, they are reported as subdatasets.

The connection string for a given subdataset/HDU is `FITS:"filename.fits":hdu_number`

6.41.2 Binary table support

Starting with GDAL 3.2, binary tables will be exposed as vector layers (update and creation support from GDAL 3.2.1).

The FITS data types are mapped to OGR data types as the following:

Table 2: Data types

TFORM value	TSCAL, TOFFSET value	Occurrence count
'L' (Logical)	ignored	1
'L' (Logical)	ignored	> 1
'X' (bit)	ignored	each bit mapped to a OGR field
'B' (unsigned byte)	1, 0 (unsigned byte) or 1, -128 (signed byte)	1
'B' (unsigned byte)	1, 0 (unsigned byte) or 1, -128 (signed byte)	> 1
'I' (16 bit signed integer)	1, 0	1
'I' (16 bit integer, interpreted as unsigned)	1, 32768	1
'I' (16 bit signed integer)	other than (1,0) and (1,32768)	1
'I' (16 bit integer)	1, 0	>1
'I' (16 bit integer, interpreted as unsigned)	1, 32768	>1
'I' (16 bit signed integer)	other than (1, 0) and (1, 32768)	> 1
'J' (32 bit signed integer)	1, 0	1
'J' (32 bit integer, interpreted as unsigned)	1, 2147483648	1
'J' (32 bit signed integer)	other than (1, 0) and (1, 2147483648)	1
'J' (32 bit integer)	1, 0	>1
'J' (32 bit integer, interpreted as unsigned)	1, 2147483648	>1
'J' (32 bit signed integer)	other than (1, 0) and (1, 2147483648)	> 1
'K' (64 bit signed integer)	1, 0	1
'K' (64 bit signed integer)	other than (1, 0)	1
'K' (64 bit signed integer)	1, 0	> 1
'K' (64 bit signed integer)	other than (1, 0)	> 1
'A' (character)	ignored	if TFORM='Axxx' and no TDIM header
'A' (character)	ignored	TDIM for 2D field, or variable length ('PA
'E' (single precision floating point)	1, 0	1
'E' (single precision floating point)	other than (1, 0)	1
'E' (single precision floating point)	1, 0	> 1
'E' (single precision floating point)	other than (1, 0)	> 1
'D' (double precision floating point)	any	1
'D' (double precision floating point)	any	> 1
'C' (single precision complex)	any	1
'C' (single precision complex)	any	> 1
'M' (double precision complex)	any	1
'M' (double precision complex)	any	> 1

Fields with a repeat count > 1 expressing fixed size arrays, or fields using array descriptors 'P' and 'Q' for variable length arrays are mapped to OGR OFTxxxxxList data types. The potential 2D structure of such field has no direct equivalence in OGR, so OGR will expose a linear structure. For fixed size arrays, the user can retrieve the value of the TDIMxx header in the layer metadata to recover the dimensionality of the field.

Fields that have TSCAL and/or TZERO headers are automatically scaled and offset to the physical value (only applies to numeric data types)

TNULL headers are used for integer numeric data types and for a single-occurrence field to set a OGR field to NULL.

6.41.3 Layer creation options

Layer creation options can be specified in command-line tools using the syntax `-lco <NAME>=<VALUE>` or by providing the appropriate arguments to *GDALDatasetCreateLayer()* (C) or *Dataset.CreateLayer* (Python). The following layer creation options are available:

- **REPEAT_{fieldname}=<integer>:** For a given field (substitute {fieldname} by its name) of type IntegerList, Integer64List or RealList, specify a fixed number of elements. Otherwise those fields will be created as variable-length FITS columns, which can have performance impact on creation.
- **COMPUTE_REPEAT=[AT_FIELD_CREATION/AT_FIRST_FEATURE_CREATION]:** Defaults to `AT_FIELD_CREATION`. For fields of type IntegerList, Integer64List or RealList, specifies when they are mapped to a FITS column type. The default is AT_FIELD_CREATION, and implies that they will be created as variable-length FITS columns, unless a *REPEAT_{fieldname}* option is specified. When AT_FIRST_FEATURE_CREATION is specified, the number of elements in the first feature will be taken into account to create fixed-size FITS columns.

When using ogr2ogr or *GDALVectorTranslate()* with a FITS source, the FITS header will be taken into account, in particular to help to determine the FITS data type of target columns.

6.41.4 Examples

- Listing subdatasets in a MEF .fits:

```
$ gdalinfo ../autotest/gdrivers/data/fits/image_in_first_and_second_hdu.fits

Driver: FITS/Flexible Image Transport System
Files: ../autotest/gdrivers/data/fits/image_in_first_and_second_hdu.fits
Size is 512, 512
Metadata:
EXTNAME=FIRST_IMAGE
Subdatasets:
SUBDATASET_1_NAME=FITS:"../autotest/gdrivers/data/fits/image_in_first_and_
↪second_hdu.fits":1
SUBDATASET_1_DESC=HDU 1 (1x2, 1 band), FIRST_IMAGE
SUBDATASET_2_NAME=FITS:"../autotest/gdrivers/data/fits/image_in_first_and_
↪second_hdu.fits":2
SUBDATASET_2_DESC=HDU 2 (1x3, 1 band)
Corner Coordinates:
Upper Left  (    0.0,    0.0)
Lower Left  (    0.0,  512.0)
Upper Right (  512.0,    0.0)
Lower Right (  512.0,  512.0)
Center      (  256.0,  256.0)
```

- Opening a given raster HDU:

```
$ gdalinfo FITS:"../autotest/gdrivers/data/fits/image_in_first_and_second_
↪hdu.fits":1

Driver: FITS/Flexible Image Transport System
Files: none associated
Size is 1, 2
Metadata:
EXTNAME=FIRST_IMAGE
Corner Coordinates:
Upper Left  (    0.0,    0.0)
Lower Left  (    0.0,    2.0)
Upper Right (    1.0,    0.0)
Lower Right (    1.0,    2.0)
Center      (    0.5,    1.0)
Band 1 Block=1x1 Type=Byte, ColorInterp=Undefined
```

- Listing potential binary tables in a FITS file:

```
$ ogrinfo my.fits
```

- Converting a GeoPackage layer into a FITS binary table:

```
$ ogr2ogr out.fits my.gpkg my_table
```

6.41.5 Other

NOTE: Implemented as fitsdataset.cpp.

6.41.6 Notes on CFITSIO linking in GDAL

6.41.6.1 Linux

From source

Install CFITSIO headers from your distribution (eg, cfitsio-devel on Fedora; libcfitsio-dev on Debian-Ubuntu), then compile GDAL as usual. CFITSIO will be automatically detected and linked.

From distributions

On Fedora/CentOS install CFITSIO then GDAL with dnf (yum): cfitsio is automatically linked.

6.41.6.2 MacOSX

The last versions of the MacOSX packages are not linked against CFITSIO. Install CFITSIO as described in the official documentation.

6.41.7 Driver capabilities

Supports CreateCopy()

This driver supports the *GDALDriver::CreateCopy()* operation

Supports Create()

This driver supports the *GDALDriver::Create()* operation

Supports Georeferencing

This driver supports georeferencing

Supports VirtualIO

This driver supports *virtual I/O operations (/vsimem/, etc.)*

6.42 GenBin -- Generic Binary (.hdr labelled)

Driver short name

GenBin

Driver built-in by default

This driver is built-in by default

This driver supporting reading "Generic Binary" files labelled with a .hdr file, but distinct from the more common ESRI labelled .hdr format (EHdr driver). The origin of this format is not entirely clear. The .hdr files supported by this driver are look something like this:

```
{{{
BANDS:       1
ROWS:     6542
COLS:     9340
...
}}}
```

Pixel data types of U8, U16, S16, F32, F64, and U1 (bit) are supported. Georeferencing and coordinate system information should be supported when provided.

NOTE: Implemented as genbindataset.cpp.

6.42.1 Driver capabilities

Supports VirtualIO

This driver supports *virtual I/O operations (/vsimem/, etc.)*

6.43 Oracle Spatial GeoRaster

Driver short name

GeoRaster

Build dependencies

Oracle client libraries

This driver supports reading and writing raster data in Oracle Spatial GeoRaster format (10g or later). The Oracle Spatial GeoRaster driver is optionally built as a GDAL plugin, but it requires Oracle client libraries.

When opening a GeoRaster, its name should be specified in the form:

georaster:<user>{,/}<pwd>{,@}[db],[schema.][table],[column],[where]
georaster:<user>{,/}<pwd>{,@}[db],<rdt>,<rid>

Where:

user = Oracle server user name, when a proxy user is used, it is in the format of proxyuser[username].
pwd = user password, double quote the password when the password has '@' or ',', or the password is case-sensitive.
db = Oracle Net connect identifier. This can be the TNS alias defined in the tnsnames.ora, or a quoted string of Oracle Net connect descriptor. The location of the tnsnames.ora is configured by TNS_ADMIN environment variable.
schema = name of a schema
table = name of a GeoRaster table (table that contains GeoRaster columns)
column = name of a column data type MDSYS.SDO_GEORASTER
where = a simple where clause to identify one or multiple GeoRaster(s)
rdt = name of a raster data table
rid = numeric identification of one GeoRaster

Examples:

geor:scott,tiger,demodb,table,column,id=1
geor:scott,tiger,demodb,table,column,"id = 1"
geor:gisuser[scott]/welcome,demodb,table,column,"id = 1"
geor:/@demodb,table,column,"id = 1"

geor:scott/\"Welcome@Tiger\"@"(description=(retry_count=20)(retry_delay=3)(address=(protocol=tcps)(port=1522)(host=adb.ca-toronto-1.oraclecloud.com))(connect_data=(service_name=g0eab5a4f6c8694_low.adb.oraclecloud.com))(security=(ssl_server_dn_match=yes)(
"georaster:scott/tiger@demodb,table,column,gain>10"
"georaster:scott/tiger@demodb,table,column,city='Brasilia'"
georaster:scott,tiger,,rdt_10$,10

geor:scott/tiger,,rdt_10$,10

Note: Do not use space around the field values and the commas.

Note: The third example shows that the proxy user `gisuser` is used to connect to user `scott` The password `welcome` is the password to the proxy user `gisuser`

Note: The fourth example shows how to connect when the database user credentials are stored in a client-side Oracle wallet.

Note: The fifth example shows how to double quote the case-sensitive password and the password that contains '@', this example also shows how to use the Oracle Net connect descriptor to connect to an Oracle ADB.

Note: In the last two examples, the Oracle Net connect identifier is left empty (",,") because it is connecting to a local database that is configured in the environment.

Note: If the query results in more than one GeoRaster it will be treated as a GDAL metadata's list of sub-datasets (see below)

6.43.1 Driver capabilities

Supports CreateCopy()

This driver supports the *`GDALDriver::CreateCopy()`* operation

Supports Create()

This driver supports the *`GDALDriver::Create()`* operation

Supports Georeferencing

This driver supports georeferencing

Supports VirtualIO

This driver supports *virtual I/O operations (/vsimem/, etc.)*

6.43.2 Browsing the database for GeoRasters

By providing some basic information the GeoRaster driver is capable of listing the existing rasters stored on the server:

To list all the GeoRaster table on the server that belongs to that user name and database:

```
gdalinfo georaster:scott/tiger@db1
```

To list all the GeoRaster type columns that exist in that table:

```
gdalinfo georaster:scott/tiger@db1,table_name
```

That will list all the GeoRaster objects stored in that table.

```
gdalinfo georaster:scott/tiger@db1,table_name,georaster_column
```

That will list all the GeoRaster existing on that table according to a Where clause.

```
gdalinfo georaster:scott/tiger@db1,table_name,georaster_column,city='Brasilia'
```

Note that the result of those queries are returned as GDAL metadata sub-datasets, e.g.:

```
gdalinfo georaster:scott/tiger
# Driver: GeoRaster/Oracle Spatial GeoRaster
# Subdatasets:
# SUBDATASET_1_NAME=georaster:scott,tiger,,LANDSAT
# SUBDATASET_1_DESC=Table:LANDSAT
# SUBDATASET_2_NAME=georaster:scott,tiger,,GDAL_IMPORT
# SUBDATASET_2_DESC=Table:GDAL_IMPORT
```

6.43.3 Creation Options

Creation options can be specified in command-line tools using the syntax `-co <NAME>=<VALUE>` or by providing the appropriate arguments to *GDALCreate()* (C) or *Driver.Create* (Python). The following creation options are supported:

- **BLOCKXSIZE=value:** The number of pixel columns per raster block.
- **BLOCKYSIZE=value:** The number of pixel rows per raster block.
- **BLOCKBSIZE=value:** The number of bands per raster block.
- **BLOCKING=value:** Decline the use of blocking (NO) or request an automatic blocking size (OPTIMAL-PADDING).
- **SRID=value:** Assign a specific EPSG projection/reference system identification to the GeoRaster.
- **INTERLEAVE=[BAND/LINE/PIXEL]:** Band interleaving mode, BAND, LINE, PIXEL (or BSQ, BIL, BIP) for band sequential, Line or Pixel interleaving. Starting with GDAL 3.5, when copying from a source dataset with multiple bands which advertises a INTERLEAVE metadata item, if the INTERLEAVE creation option is not specified, the source dataset INTERLEAVE will be automatically taken into account, unless the *COMPRESS* creation option is specified.
- **DESCRIPTION=value:** A simple description of a newly created table in SQL syntax. If the table already exist, this create option will be ignored, e.g.:

  ```
  gdal_translate -of georaster landsat_823.tif geor:scott/tiger@orcl,landsat,raster \
    -co DESCRIPTION="(ID NUMBER, NAME VARCHAR2(40), RASTER MDSYS.SDO_GEORASTER)" \
    -co INSERT="VALUES (1,'Scene 823',SDO_GEOR.INIT())"
  ```

- **INSERT=value:** A simple SQL insert/values clause to inform the driver what values to fill up when inserting a new row on the table, e.g.:

  ```
  gdal_translate -of georaster landsat_825.tif geor:scott/tiger@orcl,landsat,raster \
    -co INSERT="(ID, RASTER) VALUES (2,SDO_GEOR.INIT())"
  ```

- **GENPYRAMID=value:** Generate pyramid after a GeoRaster object have been loaded to the database. The content of that parameter must be the resampling method of choice NN (nearest neighbor) , BILINEAR, BI-QUADRATIC, CUBIC, AVERAGE4 or AVERAGE16. If *GENPYRLEVELS* is not informed the PL/SQL function sdo_geor.generatePyramid will calculate the number of levels to generate.

- **GENPYRLEVELS=value:** Define the number of pyramid levels to be generated. If *GENPYRAMID* is not informed the resample method NN (nearest neighbor) will apply.
- **GENSTATS=[TRUE/FALSE]:** Defaults to FALSE. To generate statistics from the given rasters, set this value to TRUE. Default value is FALSE. This option must be present in order to generate the stats, otherwise, other GENSTATS options are ignored.
- **GENSTATS_SAMPLINGFACTOR=<integer>:** Defaults to 1. Defines the number of cells skipped in both row and column dimensions when the statistics are computed. For example, when setting this value to 4, one-sixteenth of the cells are sampled. The higher the value, the less accurate the statistics are likely to be, but the more quickly they will be computed. Defaults to 1, which means that all cells are sampled.
- **GENSTATS_SAMPLINGWINDOW=<integer,integer,integer,integer>:** This parameter identifies the upper-left (row, column) and lower-right (row, column) coordinates of a rectangular window, and raster space is assumed. The intersection of the MBR (minimum bounding rectangle) of the GeoRaster object in raster space is used for computing statistics. When this value is not specified, statistics are computed for the entire raster.
- **GENSTATS_HISTOGRAM=[TRUE/FALSE]:** Defaults to FALSE. When this value is set to TRUE, a histogram will be computed and stored. Defaults to FALSE, so a histogram won't be generated.
- **GENSTATS_LAYERNUMBERS=[<integer,integer,...>/<integer>-<integer>]:** Defines the numbers of the layers for which to compute the statistics. This can include numbers, ranges (indicated by hyphens), and commas to separate any combination of those. For example, '1,3-5,7', '1,3,6', '1-6'. If this value is not specified, statistics will be computed for all layers.
- **GENSTATS_USEBIN=[TRUE/FALSE]:** Defaults to TRUE. Defaults to TRUE. Specifies whether or not to use a provided bin function (specified in *GENSTATS_BINFUNCTION*). When this value is set to TRUE, the bin function to be used follows the following sequence: (1) the bin function specified in *GENSTATS_BINFUNCTION*. (2) the bin function specified by the <binFunction> element in the GeoRaster XML metadata. (3) a dynamically generated bin function generated as follows: Min and max are the actual min and max values of the raster Numbins is defined as: * celldepth = 1, numbins = 2. * cellDepth = 2, numbins = 4. * cellDepth = 4, numbins = 8. * cellDepth >= 8, numbins = 256. When this value is set to FALSE, then the bin function to use is the one generated dynamically as previously described.
- **GENSTATS_BINFUNCTION=<integer,integer,integer,integer,integer>:** An array whose element specify the bin type, total number of bins, first bin number, minimum cell value, and maximum cell value. Bin type must be linear (0). When this value is not specified, and *GENSTATS_USEBIN* is TRUE, then the bin function to use is as follows:
  1. A valid function defined in the GeoRaster metadata.
  2. The same bin function generated when *GENSTATS_USEBIN* is FALSE.
- **GENSTATS_NODATA=[TRUE/FALSE]:** Defaults to FALSE. Specifies whether or not to compare each cell values with NODATA values defined in the metadata when computing statistics. When set to TRUE, all pixels with a NODATA value won't be considered. When set to FALSE, NODATA pixels will be considered as regular pixels. A NODATA value is used for cells whose values are either not known or meaningless
- **COMPRESS=[JPEG-F/JP2-F/DEFLATE/NONE]:** Compression options. The JPEG-F options is lossy, meaning that the original pixel values are changed. The JP2-F compression is lossless if *JP2_QUALITY=100*.
- **QUALITY=0-100:** Defaults to 75. Quality compression option for JPEG ranging from 0 to 100.
- **JP2_QUALITY=<float_value,float_value,...>:** Only if *COMPRESS=JP2-f*. Percentage between 0 and 100. A value of 50 means the file will be half-size in comparison to uncompressed data, 33 means 1/3, etc.. Defaults to 25 (unless the dataset is made of a single band with color table, in which case the default quality is 100).
- **JP2_REVERSIBLE=[YES/NO]:** Only if *COMPRESS=JP2-f*. YES means use of reversible 5x3 integer-only filter, NO use of the irreversible DWT 9-7. Defaults to NO (unless the dataset is made of a single band with color table, in which case reversible filter is used).

- **JP2_RESOLUTIONS=<integer>:** Only if *COMPRESS=JP2-f*. Number of resolution levels. Default value is selected such the smallest overview of a tile is no bigger than 128x128.
- **JP2_BLOCKXSIZE=<integer>:** Defaults to 1024. Only if *COMPRESS=JP2-f*. Tile width.
- **JP2_BLOCKYSIZE=<integer>:** Defaults to 1024. Only if *COMPRESS=JP2-f*. Tile height.
- **JP2_PROGRESSION=[LRCP/RLCP/RPCL/PCRL/CPRL]:** Defaults to LRCP. Only if *COMPRESS=JP2-f*. Progression order.
- **NBITS=[1/2/4]:** Sub byte data type.
- **SPATIALEXTENT=[TRUE/FALSE]:** Defaults to TRUE. Generate Spatial Extents. The default value is TRUE, which means that this option only need to be set to force the Spatial Extent to remain as NULL. If *EXTENTSRID* is not set the Spatial Extent geometry will be generated with the same SRID as the GeoRaster object.
- **EXTENTSRID=value:** SRID code to be used on the Spatial Extent geometry. If the table/column has already a spatial index, the value specified should be the same as the SRID on the Spatial Extents of the other existing GeoRaster objects, on which the spatial index is built.
- **OBJECTTABLE=[TRUE/FALSE]:** Defaults to FALSE. To create RDT as SDO_RASTER object set to TRUE. Otherwise, the RDT will be created as regular relational tables. That does not apply for Oracle version older than 11.
- **POOL=[TRUE/FALSE]:** Defaults to FALSE. When this option is set to TRUE, OCI session pool is created and associated with the GeoRaster driver. The session pool is destroyed when the GeoRaster driver is destroyed. This option can be used to improve the performance of the GeoRaster driver in GDAL APIs.
- **POOL_SESSMIN=value:** Defaults to 1. Only if *POOL=TRUE*. The number of the sessions are started when a session pool is created.
- **POOL_SESSMAX=value:** Defaults to 10. Only if *POOL=TRUE*. The maximum number of the sessions that can be opened in a session pool. Must be greater than 0.
- **POOL_SESSINCR=value:** Defaults to 2. Only if *POOL=TRUE*. The next increment number for the sessions to be started if the current number of sessions is less than POOL_SESSMAX. Must be greater than 0.

6.43.4 Open Options

Open options can be specified in command-line tools using the syntax `-oo <NAME>=<VALUE>` or by providing the appropriate arguments to *GDALOpenEx()* (C) or *gdal.OpenEx* (Python). The following open options are supported:

- **POOL=[TRUE/FALSE]:** Defaults to FALSE. When this option is set to TRUE, OCI session pool is created and associated with the GeoRaster driver. The session pool is destroyed when the GeoRaster driver is destroyed. This option can be used to improve the performance of the GeoRaster driver when there are concurrent reading through the GeoRaster driver in GDAL APIs.
- **POOL_SESSMIN=value:** Defaults to 1. Only if *POOL=TRUE*. The number of the sessions are started when a session pool is created.
- **POOL_SESSMAX=value:** Defaults to 10. Only if *POOL=TRUE*. The maximum number of the sessions that can be opened in a session pool. Must be greater than 0.
- **POOL_SESSINCR=value:** Defaults to 2. Only if *POOL=TRUE*. The next increment number for the sessions to be started if the current number of sessions is less than POOL_SESSMAX. Must be greater than 0.

6.43.5 Importing GeoRaster

During the process of importing raster into a GeoRaster object it is possible to give the driver a simple SQL table definition and also a SQL insert/values clause to inform the driver about the table to be created and the values to be added to the newly created row. The following example does that:

```
gdal_translate -of georaster Newpor.tif georaster:scott/tiger,,landsat,scene \
  -co "DESCRIPTION=(ID NUMBER, SITE VARCHAR2(45), SCENE MDSYS.SDO_GEORASTER)" \
  -co "INSERT=VALUES(1,'West fields', SDO_GEOR.INIT())" \
  -co "BLOCKXSIZE=512" -co "BLOCKYSIZE=512" -co "BLOCKBSIZE=3" \
  -co "INTERLEAVE=PIXEL" -co "COMPRESS=JPEG-F"
```

Note that the create option DESCRIPTION requires to inform table name (in bold). And column name (underlined) should match the description:

```
gdal_translate -of georaster landsat_1.tif georaster:scott/tiger,,landsat,scene \
  -co "DESCRIPTION=(ID NUMBER, SITE VARCHAR2(45), SCENE MDSYS.SDO_GEORASTER)" \
  -co "INSERT=VALUES(1,'West fields', SDO_GEOR.INIT())"
```

If the table "landsat" exist, the option "DESCRIPTION" is ignored. The driver can only update one GeoRaster column per run of gdal_translate. Oracle create default names and values for RDT and RID during the initialization of the SDO_GEORASTER object but user are also able to specify a name and value of their choice.

```
gdal_translate -of georaster landsat_1.tif georaster:scott/tiger,,landsat,scene \
  -co "INSERT=VALUES(10,'Main building', SDO_GEOR.INIT('RDT', 10))"
```

If no information is given about where to store the raster the driver will create (if doesn't exist already) a default table named GDAL_IMPORT with just one GeoRaster column named RASTER and a table GDAL_RDT as the RDT, the RID will be given automatically by the server, example:

```
gdal_translate -of georaster input.tif “geor:scott/tiger@dbdemo”
```

6.43.6 Exporting GeoRaster

A GeoRaster can be identified by a Where clause or by a pair of RDT & RID:

```
gdal_translate -of gtiff geor:scott/tiger@dbdemo,landsat,scene,id=54 output.tif
gdal_translate -of gtiff geor:scott/tiger@dbdemo,st_rdt_1,130 output.tif
```

6.43.7 Cross schema access

As long as the user was granted full access the GeoRaster table and the Raster Data Table, e.g.:

```
% sqlplus scott/tiger
SQL> grant select,insert,update,delete on gdal_import to spock;
SQL> grant select,insert,update,delete on gdal_rdt to spock;
```

It is possible to an user access to extract and load GeoRaster from another user/schema by informing the schema name as showed here:

Browsing:

```
gdalinfo geor:spock/lion@orcl,scott.
gdalinfo geor:spock/lion@orcl,scott.gdal_import,raster,"t.raster.rasterid > 100"
gdalinfo geor:spock/lion@orcl,scott.gdal_import,raster,t.raster.rasterid=101
```

Extracting:

```
gdal_translate geor:spock/lion@orcl,scott.gdal_import,raster,t.raster.rasterid=101out.tif
gdal_translate geor:spock/lion@orcl,gdal_rdt,101 out.tif
```

Note: On the above example that accessing by RDT/RID doesn't need same name as long as the users is granted full access to both tables.

Loading:

```
gdal_translate -of georaster input.tif geor:spock/lion@orcl,scott.
gdal_translate -of georaster input.tif geor:spock/lion@orcl,scott.cities,image \
  -co INSERT="(1,'Rio de Janeiro',sdo_geor.init('cities_rdt'))"
```

6.43.8 General use of GeoRaster

GeoRaster can be used in any GDAL command line tool with all the available options. Like a image subset extraction or re-project:

```
 % gdal_translate -of gtiff geor:scott/tiger@dbdemo,landsat,scene,id=54 output.tif \
 -srcwin 0 0 800 600
 % gdalwarp -of png geor:scott/tiger@dbdemo,st_rdt_1,130 output.png
-t_srs EPSG:9000913
```

Two different GeoRaster can be used as input and output on the same operation:

```
% gdal_translate -of georaster geor:scott/tiger@dbdemo,landsat,scene,id=54 \
geor:scott/tiger@proj1,projview,image -co INSERT="VALUES (102, SDO_GEOR.INIT())"
```

Applications that use GDAL can theoretically read and write from GeoRaster just like any other format but most of then are more inclined to try to access files on the file system so one alternative is to create VRT to represent the GeoRaster description, e.g.:

```
% gdal_translate -of VRT geor:scott/tiger@dbdemo,landsat,scene,id=54 view_54.vrt
% openenv view_54.vrt
```

6.43.8.1 Standalone plugin compilation

Added in version 3.10.

While this driver may be built as part of a whole GDAL build, either in libgdal itself, or as a plugin, it is also possible to only build this driver as a plugin, against an already built libgdal.

The version of the GDAL sources used to build the driver must match the version of the libgdal it is built against.

For example, from a "build_georaster" directory under the root of the GDAL source tree:

```
cmake -S ../frmts/georaster -DCMAKE_PREFIX_PATH=/path/to/GDAL_installation_prefix -
↪DOracle_ROOT=/path/to/instantclient_sdk_root
cmake --build .
```

Note that such a plugin, when used against a libgdal not aware of it, will be systematically loaded at GDAL driver initialization time, and will not benefit from *deferred plugin loading capabilities <rfc-96>*. For that, libgdal itself must be built with the CMake variable GDAL_REGISTER_DRIVER_GEOR_FOR_LATER_PLUGIN=ON set.

6.44 GFF -- Sandia National Laboratories GSAT File Format

Driver short name

GFF

Driver built-in by default

This driver is built-in by default

This read-only GDAL driver is designed to provide access to processed data from Sandia National Laboratories' various experimental sensors. The format is essentially an arbitrary length header containing instrument configuration and performance parameters along with a binary matrix of 16- or 32-bit complex or byte real data.

The GFF format was implemented based on the Matlab code provided by Sandia to read the data. The driver supports all types of data (16-bit or 32-bit complex, real bytes) theoretically, however due to a lack of data only 32-bit complex data has been tested.

Sandia provides some sample data at http://www.sandia.gov/radar/complex-data/.

The extension for GFF formats is .gff.

NOTE: Implemented as gff_dataset.cpp.

6.44.1 Driver capabilities

Supports VirtualIO

This driver supports *virtual I/O operations (/vsimem/, etc.)*

6.45 GIF -- Graphics Interchange Format

Driver short name

GIF

Build dependencies

(internal GIF library provided)

GDAL supports reading and writing of normal, and interlaced GIF files. Gif files always appear as having one colormapped eight bit band. GIF files have no support for georeferencing.

A GIF image with transparency will have that entry marked as having an alpha value of 0.0 (transparent). Also, the transparent value will be returned as the NoData value for the band.

If an ESRI *world file* exists with the .gfw, .gifw or .wld extension, it will be read and used to establish the geotransform for the image.

XMP metadata can be extracted from the file, and will be stored as XML raw content in the xml:XMP metadata domain.

6.45.1 Driver capabilities

Supports CreateCopy()

This driver supports the `GDALDriver::CreateCopy()` operation

Supports VirtualIO

This driver supports *virtual I/O operations (/vsimem/, etc.)*

6.45.2 Creation Issues

GIF files can only be created as 1 8bit band using the "CreateCopy" mechanism. If written from a file that is not colormapped, a default greyscale colormap is generated. Transparent GIFs are not currently supported on creation.

Creation options can be specified in command-line tools using the syntax `-co <NAME>=<VALUE>` or by providing the appropriate arguments to *`GDALCreate()`* (C) or *`Driver.Create`* (Python). The following creation options are supported:

- **WORLDFILE=[ON/OFF]:** Defaults to `OFF`. Force the generation of an associated ESRI world file (.wld). See *World Files* section for details.
- **INTERLACING=[ON/OFF]:** Defaults to `OFF`. Generate an interlaced (progressive) GIF file.

GDAL's internal GIF support is implemented based on source from the giflib 4.1.6 library (written by Gershon Elbor, Eric Raymond and Toshio Kuratomi), hence generating LZW compressed GIF.

The driver was written with the financial support of the DM Solutions Group, and CIET International.

6.46 GPKG -- GeoPackage raster

Driver short name

GPKG

Build dependencies

libsqlite3 (and any or all of PNG, JPEG, WEBP drivers)

This driver implements full read/creation/update of tables containing raster tiles in the OGC GeoPackage format standard. The GeoPackage standard uses a SQLite database file as a generic container, and the standard defines:

- Expected metadata tables (`gpkg_contents`, `gpkg_spatial_ref_sys`, `gpkg_tile_matrix`, `gpkg_tile_matrix_set`, ...)
- Tile format encoding (PNG and JPEG for base specification, WebP as extension) and tiling conventions
- Naming and conventions for extensions

This driver reads and writes SQLite files from the file system, so it must be run by a user with read/write access to the files it is working with.

The driver can also handle GeoPackage vectors. See *GeoPackage vector* documentation page

Various kind of input datasets can be converted to GeoPackage raster :

- Single band grey level

- Single band with R,G,B or R,G,B,A color table
- Two bands: first band with grey level, second band with alpha channel
- Three bands: Red, Green, Blue
- Four band: Red, Green, Blue, Alpha

GeoPackage rasters only support Byte data type.

All raster extensions standardized by the GeoPackage specification are supported in read and creation :

- *gpkg_webp*: when storing WebP tiles, provided that GDAL is compiled against libwebp.
- *gpkg_zoom_other*: when resolution of consecutive zoom levels does not vary with a factor of 2.

Validation whether a GeoPackage file conforms to the GeoPackage specification can be done with *gdal driver gpkg validate*.

6.46.1 Driver capabilities

Supports CreateCopy()

This driver supports the `GDALDriver::CreateCopy()` operation

Supports Create()

This driver supports the `GDALDriver::Create()` operation

Supports Georeferencing

This driver supports georeferencing

Supports VirtualIO

This driver supports *virtual I/O operations (/vsimem/, etc.)*

6.46.2 Opening options

By default, the driver will expose a GeoPackage dataset as a four band (Red,Green, Blue,Alpha) dataset, which gives the maximum compatibility with the various encodings of tiles that can be stored. It is possible to specify an explicit number of bands with the BAND_COUNT opening option. Starting with GDAL 3.6, a special metadata item is written when creating a GeoPackage raster with GDAL (when using the default CUSTOM tiling scheme), and it is used on reading as the default number of bands.

The driver will use the geographic/projected extent indicated in the gpkg_contents table, and do necessary clipping, if needed, to respect that extent. However that information being optional, if omitted, the driver will use the extent provided by the gpkg_tile_matrix_set, which covers the extent at all zoom levels. The user can also specify the USE_TILE_EXTENT=YES open option to use the actual extent of tiles at the maximum zoom level. Or it can specify any of MINX/MINY/MAXX/MAXY to have a custom extent.

Open options can be specified in command-line tools using the syntax `-oo <NAME>=<VALUE>` or by providing the appropriate arguments to `GDALOpenEx()` (C) or `gdal.OpenEx` (Python). The following open options are available:

- **TABLE=<table_name>:** Name of the table containing the tiles (called "Tile Pyramid User Data Table" in the GeoPackage specification language). If the GeoPackage dataset only contains one table, this option is not necessary. Otherwise, it is required.
- **ZOOM_LEVEL=value:** Integer value between 0 and the maximum filled in the *gpkg_tile_matrix* table. By default, the driver will select the maximum zoom level, such as at least one tile at that zoom level is found in the raster table.
- **BAND_COUNT=[AUTO/1/2/3/4]:** Number of bands of the dataset exposed after opening. Only used for Byte data type. Some conversions will be done when possible and implemented, but this might fail in some cases, depending on the BAND_COUNT value and the number of bands of the tile. Before GDAL 3.6, the default value is 4 (which is the always safe value). Starting with GDAL 3.6, when the metadata of the file contains an hint of the number of bands, this one is used in AUTO mode (default value), or fallback to 4 when it is not present.
- **MINX=value:** Minimum longitude/easting of the area of interest.
- **MINY=value:** Minimum latitude/northing of the area of interest.
- **MAXX=value:** Maximum longitude/easting of the area of interest.
- **MAXY=value:** Maximum latitude/northing of the area of interest.
- **USE_TILE_EXTENT=[YES/NO]:** Defaults to `NO`. Whether to use the extent of actual existing tiles at the zoom level of the full resolution dataset.
- **TILE_FORMAT=[PNG_JPEG/PNG/PNG8/JPEG/WEBP]:** Format used to store tiles. See *Tile formats*. Only used in update mode and for Byte data type. Defaults to PNG_JPEG, unless, starting with GDAL 3.6, if the raster has one band, in which case PNG is used.
- **QUALITY=1-100:** Defaults to `75`. Quality setting for JPEG and WEBP compression. Only used in update mode.
- **ZLEVEL=1-9:** Defaults to `6`. DEFLATE compression level for PNG tiles. Only used in update mode.
- **DITHER=[YES/NO]:** Defaults to `NO`. Whether to use Floyd-Steinberg dithering (for *`TILE_FORMAT=PNG8`*). Only used in update mode.

Note: open options are typically specified with "-oo name=value" syntax in most GDAL utilities, or with the GDALOpenEx() API call.

6.46.3 Creation issues

Depending of the number of bands of the input dataset and the tile format selected, the driver will do the necessary conversions to be compatible with the tile format.

To add several tile tables to a GeoPackage dataset (seen as GDAL subdatasets), or to add a tile table to an existing vector-only GeoPackage, the generic APPEND_SUBDATASET=YES creation option must be provided.

Fully transparent tiles will not be written to the database, as allowed by the format.

The driver implements the Create() and IWriteBlock() methods, so that arbitrary writing of raster blocks is possible, enabling the direct use of GeoPackage as the output dataset of utilities such as gdalwarp.

On creation, raster blocks can be written only if the geotransformation matrix has been set with SetGeoTransform() This is effectively needed to determine the zoom level of the full resolution dataset based on the pixel resolution, dataset and tile dimensions.

Technical/implementation note: when a dataset is opened with a non-default area of interest (i.e. use of MINX,MINY,MAXX,MAXY or USE_TILE_EXTENT open option), or when creating/ opening a dataset with a non-custom tiling scheme, it is possible that GDAL blocks do not exactly match a single GeoPackage tile. In which case, each GDAL block will overlap four GeoPackage tiles. This is easily handled on the read side, but on creation/update side, such configuration could cause numerous decompression/ recompression of tiles to be done, which might cause

unnecessary quality loss when using lossy compression (JPEG, WebP). To avoid that, the driver will create a temporary database next to the main GeoPackage file to store partial GeoPackage tiles in a lossless (and uncompressed) way. Once a tile has received data for its four quadrants and for all the bands (or the dataset is closed or explicitly flushed with FlushCache()), those uncompressed tiles are definitely transferred to the GeoPackage file with the appropriate compression. All of this is transparent to the user of GDAL API/utilities

The driver updates the GeoPackage `last_change` timestamp when the file is created or modified. If consistent binary output is required for reproducibility, the timestamp can be forced to a specific value by setting the *OGR_CURRENT_DATE* global configuration option. When setting the option, take care to meet the specific time format requirement of the GeoPackage standard, e.g. for version 1.2.

6.46.3.1 Tile formats

Tiled rasters

This section only applies for raster of Byte data type.

GeoPackage can store tiles in different formats, PNG and/or JPEG for the baseline specification, and WebP for extended GeoPackage. Support for those tile formats depend if the underlying drivers are available in GDAL, which is generally the case for PNG and JPEG, but not necessarily for WebP since it requires GDAL to be compiled against the optional libwebp.

By default, GDAL will use a mix of PNG and JPEG tiles (PNG_JPEG tile format, or AUTO). PNG tiles will be used to store tiles that are not completely opaque, either because input dataset has an alpha channel with non fully opaque content, or because tiles are partial due to clipping at the right or bottom edges of the raster, or when a dataset is opened with a non-default area of interest, or with a non-custom tiling scheme. On the contrary, for fully opaque tiles, JPEG format will be used. Starting with GDAL 3.6, if the raster has only one band, the default is PNG.

It is possible to select one unique tile format by setting the creation/open option TILE_FORMAT to one of PNG, JPEG or WEBP. When using JPEG, the alpha channel will not be stored. When using WebP, the gpkg_webp extension will be registered. The lossy compression of WebP is used. Note that a recent enough libwebp (>=0.1.4) must be used to support alpha channel in WebP tiles.

PNG8 can be selected to use 8-bit PNG with a color table up to 256 colors. On creation, an optimized color table is computed for each tile. The DITHER option can be set to YES to use Floyd/Steinberg dithering algorithm, which spreads the quantization error on neighbouring pixels for better rendering (note however than when zooming in, this can cause non desirable visual artifacts). Setting it to YES will generally cause less effective compression. Note that at that time, such an 8-bit PNG formulation is only used for fully opaque tiles, as the median-cut algorithm currently implemented to compute the optimal color table does not support alpha channel (even if PNG8 format would potentially allow color table with transparency). So when selecting PNG8, non fully opaque tiles will be stored as 32-bit PNG.

Tiled gridded coverage data

tiled gridded coverage data can be stored using PNG unsigned 16bit tiles (with potential offset and scaling so as to be able to represent floating point data) or TIFF 32-bit floating-point LZW compressed tiles.

When converting a GDAL Int16 or UInt16 dataset, PNG tiles will be used. When converting a GDAL Float32 dataset, TIFF tiles will be used by default, unless PNG is explicitly selected, in which case scaling and offsetting will be automatically computed for each tile.

6.46.3.2 Tiling schemes

By default, conversion to GeoPackage will create a custom tiling scheme, such that the input dataset can be losslessly converted, both at the pixel and georeferencing level (if using a lossless tile format such as PNG). That tiling scheme is such that its origin (*min_x*, *max_y*) in the gpkg_tile_matrix_set table perfectly matches the top left corner of the dataset, and the selected resolution (*pixel_x_size*, *pixel_y_size*) at the computed maximum zoom_level of the gpkg_tile_matrix table will match the pixel width and height of the raster.

However to ease interoperability with other implementations, and enable use of GeoPackage with tile servicing software, it is possible to select a predefined tiling scheme that has world coverage. The available tiling schemes are :

- *GoogleMapsCompatible*, as described in WMTS 1.0 specification, Annex E.4. That tiling schemes consists of a single 256x256 tile at its zoom level 0, in EPSG:3857 CRS, with extent in easting and northing in the range [-20037508.34,20037508.34].
- *InspireCRS84Quad*, as described in Inspire View Services. That tiling schemes consists of two 256x256 tiles at its zoom level 0, in EPSG:4326 CRS, with extent in longitude in the range [-180,180] and in latitude in the range [-90,90].
- *PseudoTMS_GlobalGeodetic*, based on the global-geodetic profile of OSGeo TMS (Tile Map Service) specification. This has exactly the same definition as *InspireCRS84Quad* tiling scheme. Note however that full interoperability with TMS is not possible due to the origin of numbering of tiles being the top left corner in GeoPackage (consistently with WMTS convention), whereas TMS uses the bottom left corner as origin.
- *PseudoTMS_GlobalMercator*, based on the global-mercator profile of OSGeo TMS (Tile Map Service) specification. That tiling schemes consists of four 256x256 tiles at its zoom level 0, in EPSG:3857 CRS, with extent extent in easting and northing in the range [-20037508.34,20037508.34]. The same remark as with PseudoTMS_GlobalGeodetic applies regarding interoperability with TMS.
- *GoogleCRS84Quad*, as described in OGC 07-057r7 WMTS 1.0 specification, Annex E.3. That tiling schemes consists of a single 256x256 tile at its zoom level 0, in EPSG:4326 CRS, with extent in longitude and latitude in the range [-180,180]. Consequently, at zoom level 0, 64 lines are unused at the top and bottom of that tile. This may cause issues with some implementations of the specification, and there are some ambiguities about the exact definition of this tiling scheme. Using InspireCRS84Quad/PseudoTMS_GlobalGeodetic instead is therefore recommended. NOTE: OGC WMTS Simple Profile 13-082r2 changed the definition of GoogleCRS84Quad (so not implemented by the driver). The new definition includes a -1 level (that cannot be modeled in GeoPackage given constraints on zoom_level being positive or 0), with a single tile at origin -180,90 and whose bottom 128 lines are empty. Levels 0 or greater are identical to the InspireCRS84Quad tiling scheme. So for practical purposes, InspireCRS84Quad in GeoPackage is conformant to the new GoogleCRS84Quad definition.

In all the above tiling schemes, consecutive zoom levels defer by a resolution of a factor of two.

Starting with GDAL 3.2, it is also possible to use a Tile Matrix Set definition, encoded as a JSON file, according to the OGC Two Dimensional Tile Matrix Set standard Examples of such files can be found at http://schemas.opengis.net/tms/1.0/json/examples/ The GDAL data directory also contains files prefixed with `tms_` and with a `.json` extension. If there is a `tms_FOO.json` file, then `FOO` can be used as the value of the TILING_SCHEME creation option. There are restrictions on the types of tile matrix set supported:

- all zoom levels must have the same origin
- consecutive zoom levels defer by a resolution of a factor of two.
- all zoom levels must have the same tile dimension
- variable matrix width tile set are not supported.

6.46.3.3 Nodata value

The concept of the nodata value is only supported for tiled gridded elevation datasets. For regular tiled rasters, the alpha band must rather be used.

For Float32 datasets with TIFF tiles, the concepts of nodata in GDAL and null_value in the GeoPackage internals perfectly match.

For Int16, UInt16 or Float32 with PNG tiles, GDAL will generally remap the input nodata value to another value.

On writing, for PNG tiles, the behavior is the following one:

GDAL data type	Input GDAL nodata value	null_value in GPKG gpkg_2d_gridded_coverage_ancillary
Int16	Any	65535
UInt16	X (if coverage offset == 0 and coverage scale == 1)	X
Float32	Any	65535

On reading, for PNG tiles, the behavior is the following one:

GDAL data type	null_value in GPKG gpkg_2d_gridded_coverage_ancillary	Exposed GDAL nodata value
Int16	>= 32768	-32768
Int16	X <= 32767	X
UInt16	X	X
Float32	X	X

Thus, perfect roundtripping is achieved in the following cases:

GDAL data type	GDAL nodata value	null_value in GPKG gpkg_2d_gridded_coverage_ancillary
Int16	-32768	65535
UInt16	X (if coverage offset == 0 and coverage scale == 1)	X
Float32	65535	65535

6.46.3.4 Creation options

Creation options can be specified in command-line tools using the syntax `-co <NAME>=<VALUE>` or by providing the appropriate arguments to *`GDALCreate()`* (C) or *`Driver.Create`* (Python). The following creation options are available:

- **RASTER_TABLE=value:** Name of tile user table. By default, based on the filename (i.e. if filename is foo.gpkg, the table will be called "foo").
- **APPEND_SUBDATASET=[YES/NO]:** Defaults to `NO`. If set to YES, an existing GeoPackage will not be priorly destroyed, such as to be able to add new content to it.
- **RASTER_IDENTIFIER=value:** Human-readable identifier (e.g. short name), put in the *identifier* column of the *gpkg_contents* table.
- **RASTER_DESCRIPTION=value:** Human-readable description, put in the *description* column of the *gpkg_contents* table.
- **BLOCKSIZE=<integer>:** Defaults to `256`. Block size in width and height in pixels. Maximum supported is 4096. Should not be set when using a non-custom *`TILING_SCHEME`*.
- **BLOCKXSIZE=<integer>:** Defaults to `256`. Block width in pixels. Maximum supported is 4096.
- **BLOCKYSIZE=<integer>:** Defaults to `256`. Block height in pixels. Maximum supported is 4096.
- **TILE_FORMAT=[PNG_JPEG/PNG/PNG8/JPEG/WEBP/TIFF/AUTO]:** Defaults to `AUTO`. Format used to store tiles. See *Tile formats*.
- **QUALITY=1-100:** Defaults to `75`. Quality setting for JPEG and WEBP compression.
- **ZLEVEL=1-9:** Defaults to `6`. DEFLATE compression level for PNG tiles.

- **DITHER=[YES/NO]:** Defaults to NO. Whether to use Floyd-Steinberg dithering (for *TILE_FORMAT=PNG8*).
- **TILING_SCHEME=[CUSTOM/GoogleCRS84Quad/GoogleMapsCompatible/InspireCRS84Quad/PseudoTMS_GlobalGeodetic/PseudoTMS_GlobalMercator/other]:** Defaults to CUSTOM. See *Tiling schemes*. Starting with GDAL 3.2, the value of TILING_SCHEME can also be the filename of a JSON file according to the *OGC Two Dimensional Tile Matrix Set standard*, a URL to such file, the radical of a definition file in the GDAL data directory (e.g. FOO for a file named tms_FOO.json) or the inline JSON definition. Note: the TILING_SCHEME option with a non-CUSTOM value is best used with the gdal_translate utility / CreateCopy() API operation. If used with gdalwarp, it requires setting the -tr switch to the exact value expected by one zoom level of the tiling scheme.

  In non-CUSTOM mode, the actual resolution can be controlled with the *ZOOM_LEVEL* or *ZOOM_LEVEL_STRATEGY* options.
- **ZOOM_LEVEL=<integer>:** (GDAL >= 3.9) Zoom level number (starting at 0 for coarsest zoom level). Only used for *TILING_SCHEME* different from CUSTOM. If this option is specified, *ZOOM_LEVEL_STRATEGY* is ignored.
- **ZOOM_LEVEL_STRATEGY=[AUTO/LOWER/UPPER]:** Defaults to AUTO. Strategy to determine zoom level. Only used by CreateCopy() for *TILING_SCHEME* different from CUSTOM. LOWER will select the zoom level immediately below the theoretical computed non-integral zoom level, leading to subsampling. On the contrary, UPPER will select the immediately above zoom level, leading to oversampling. Defaults to AUTO which selects the closest zoom level.
- **RESAMPLING=[NEAREST/BILINEAR/CUBIC/CUBICSPLINE/LANCZOS/MODE/AVERAGE]:** Defaults to BILINEAR. Resampling algorithm. Only used by CreateCopy() for TILING_SCHEME different from CUSTOM. Defaults to BILINEAR.
- **PRECISION=<floating_point_value_in_vertical_units>:** Defaults to 1.0. Smallest significant value. Only used for tile gridded coverage datasets.
- **UOM=value:** Unit of Measurement. Only used for tiled gridded coverage datasets. Also set through SetUnitType()
- **FIELD_NAME=value:** Defaults to Height. Field name. Only used for tiled gridded coverage datasets.
- **QUANTITY_DEFINITION=value:** Defaults to Height. Description of the field. Only used for tiled gridded coverage datasets.
- **GRID_CELL_ENCODING=[grid-value-is-center/grid-value-is-area/grid-value-is-corner]:** Grid cell encoding. Only used for tiled gridded coverage datasets. Defaults to grid-value-is-center, when AREA_OR_POINT metadata item is not set.
- **VERSION=[AUTO/1.0/1.1/1.2/1.3/1.4]:** Set GeoPackage version (for application_id and user_version fields). In AUTO mode, this will be equivalent to 1.4 starting with GDAL 3.11 (1.2 in prior versions) 1.3 is available starting with GDAL 3.3 1.4 is available starting with GDAL 3.7.1
- **ADD_GPKG_OGR_CONTENTS=[YES/NO]:** Defaults to YES. Defines whether to add a gpkg_ogr_contents table to keep feature count for vector layers, and associated triggers.
- **CRS_WKT_EXTENSION=[YES/NO]:** (GDAL >= 3.8) Defaults to NO. Defines whether to add the definition_12_063 column to the gpkg_spatial_ref_sys system table, according to http://www.geopackage.org/spec/#extension_crs_wkt . The default is NO, unless the tile gridded coverage extension is used. With VERSION >= 1.4, a epoch column is also added. WKT strings in definition_12_063 will follow the WKT2:2015 standard when possible, but may use the WKT2:2019 standard for specific cases (dynamic CRS with coordinate epoch). This option generally does not need to be specified, as the driver will automatically update the gpkg_spatial_ref_sys table when needed, but it may be useful to create GeoPackage datasets matching the exceptions of other software or profiles (such as the DGIWG-GPKG profile).
- **METADATA_TABLES=[YES/NO]:** (GDAL >= 3.8) Defines whether to add the metadata system tables. By default, they are created on demand. If NO is specified, they are not created, even if metadata is set. If YES is

specified, they are always created.

6.46.4 Overviews

gdaladdo / BuildOverviews() can be used to compute overviews. Power-of-two overview factors (2,4,8,16,...) should be favored to be conformant with the baseline GeoPackage specification. Use of other overview factors will work with the GDAL driver, and cause the gpkg_zoom_other extension to be registered, but that could potentially cause interoperability problems with other implementations that do not support that extension.

Overviews can also be cleared with the -clean option of gdaladdo (or BuildOverviews() with nOverviews=0)

6.46.5 Metadata

GDAL uses the standardized gpkg_metadata and gpkg_metadata_reference tables to read and write metadata.

GDAL metadata, from the default metadata domain and possibly other metadata domains, is serialized in a single XML document, conformant with the format used in GDAL PAM (Persistent Auxiliary Metadata) .aux.xml files, and registered with md_scope=dataset and md_standard_uri=http://gdal.org in gpkg_metadata. In gpkg_metadata_reference, this entry is referenced with a reference_scope=table and table_name={name of the raster table}

It is possible to read and write metadata that applies to the global GeoPackage, and not only to the raster table, by using the *GEOPACKAGE* metadata domain.

Metadata not originating from GDAL can be read by the driver and will be exposed as metadata items with keys of the form GPKG_METADATA_ITEM_XXX and values the content of the *metadata* columns of the gpkg_metadata table. Update of such metadata is not currently supported through GDAL interfaces (although it can be through direct SQL commands).

The specific DESCRIPTION and IDENTIFIER metadata item of the default metadata domain can be used in read/write to read from/update the corresponding columns of the gpkg_contents table.

You can set the CREATE_METADATA_TABLES configuration option to NO to avoid creating and filling the metadata tables.

6.46.6 IMAGE_STRUCTURE metadata item

Note

Implementation details, normally transparent to GDAL users, but useful for other implementations.

Starting with GDAL 3.6.1, the following optional metadata items can be read and write into the `IMAGE_STRUCTURE` metadata domain, in the `<GDALMultiDomainMetadata>` XML element:

- BAND_COUNT=1, 2, 3 or 4. Applies only for Byte data. Set when creating a dataset so that GDAL knows the number of bands when reopening it.
- COLOR_TABLE={{r0,g0,b0,a0},...{r255,g255,b255,a255}}. Applies only for Byte data and a single band dataset. Set when creating a dataset from a source dataset that has a color table.
- TILE_FORMAT=PNG/PNG8/PNG_JPEG/JPEG/WEBP. Set when creating a dataset so that GDAL knows the tile format when reopening it, for updates.
- NODATA_VALUE=integer between 0 and 255. Applies only for Byte data.

Example:

```
INSERT INTO gpkg_metadata VALUES(
    1,
    'dataset',
    'http://gdal.org',
    'text/xml',
    '<GDALMultiDomainMetadata><Metadata domain="IMAGE_STRUCTURE"><MDI key="BAND_COUNT">1
↪</MDI><MDI key="NODATA_VALUE">255</MDI></Metadata></GDALMultiDomainMetadata>')
);
INSERT INTO gpkg_metadata_reference VALUES(
    'table','my_raster_table',NULL,NULL,'2022-11-09T18:44:59.723Z',1,NULL);
```

6.46.7 Level of support of GeoPackage Extensions

(Restricted to those have a raster scope)

Table 3: Extensions

Extension name	OGC adopted extension ?	Supported by GDAL?
Zoom Other intervals	Yes	Yes
Tiles Encoding WebP	Yes	Yes
Metadata	Yes	Yes
WKT for Coordinate Reference Systems (WKT v2)	Yes	Yes
Tiled Gridded Coverage Data	Yes	Yes

6.46.8 Examples

- Simple translation of a GeoTIFF into GeoPackage. The table 'byte' will be created with the tiles.

```
gdal_translate -of GPKG byte.tif byte.gpkg
```

- Translation of a GeoTIFF into GeoPackage using WebP tiles

```
gdal_translate -of GPKG byte.tif byte.gpkg -co TILE_FORMAT=WEBP
```

- Translation of a GeoTIFF into GeoPackage using GoogleMapsCompatible tiling scheme (with reprojection and resampling if needed)

```
gdal_translate -of GPKG byte.tif byte.gpkg -co TILING_SCHEME=GoogleMapsCompatible
```

- Building of overviews of an existing GeoPackage, and forcing JPEG tiles

```
gdaladdo -r cubic -oo TILE_FORMAT=JPEG my.gpkg 2 4 8 16 32 64
```

- Addition of a new subdataset to an existing GeoPackage, and choose a non default name for the raster table.

```
gdal_translate -of GPKG new.tif existing.gpkg -co APPEND_SUBDATASET=YES -co RASTER_
↪TABLE=new_table
```

- Reprojection of an input dataset to GeoPackage

```
gdalwarp -of GPKG in.tif out.gpkg -t_srs EPSG:3857
```

- Open a specific raster table in a GeoPackage

```
gdalinfo my.gpkg -oo TABLE=a_table
```

6.46.8.1 Raster SQL functions

The raster SQL functions mentioned at *Raster related functions* are also available.

The `gdal_get_layer_pixel_value()` function (added in GDAL 3.7), variant of the generic `gdal_get_pixel_value()`, can be used to extract the value of a pixel in a raster layer of the current dataset.

It takes 5 or 6 arguments:

- a string with the layer/table name
- a band number (numbering starting at 1)
- a string being "georef" to indicate that subsequent values will be georeferenced coordinates, or "pixel" to indicate that subsequent values will be in column, line pixel space
- georeferenced X value or column number
- georeferenced Y value or line number
- resampling method among `nearest` (default), `bilinear`, `cubic`, `cubicspline`. Optional, added in GDAL 3.10

```
SELECT gdal_get_layer_pixel_value('my_raster_table', 1, 'georef', 440720, 3751320)
SELECT gdal_get_layer_pixel_value('my_raster_table', 1, 'pixel', 0, 0)
SELECT gdal_get_pixel_value('my_raster_table', 1, 'pixel', 0.5, 0.5, 'bilinear')  --␣
↪GDAL >= 3.10
```

6.46.10 Other notes

Development of raster support in the GeoPackage driver was financially supported by Safe Software.

6.47 GRASS Raster Format

Driver short name

GRASS

Build dependencies

gdal-grass-driver

The GDAL-GRASS driver can read GRASS GIS raster maps. The driver is maintained at the GDAL-GRASS GIS driver repository.

For the driver documentation, please visit the GDAL-GRASS GIS raster driver page.

6.47.1 See Also

- GRASS GIS home page

6.48 GRASSASCIIGrid -- GRASS ASCII Grid

Driver short name

GRASSASCIIGrid

Driver built-in by default

This driver is built-in by default

Supports reading GRASS ASCII grid format (similar to Arc/Info ASCIIGRID command).

By default, the datatype returned for GRASS ASCII grid datasets by GDAL is autodetected, and set to Float32 for grid with floating point values or Int32 otherwise. This is done by analysing the format of the null value and the first 100k bytes of data of the grid. You can also explicitly specify the datatype by setting the GRASSASCIIGRID_DATATYPE configuration option (Int32, Float32 and Float64 values are supported currently)

NOTE: Implemented as aaigriddataset.cpp.

6.48.1 Driver capabilities

Supports Georeferencing

This driver supports georeferencing

Supports VirtualIO

This driver supports *virtual I/O operations (/vsimem/, etc.)*

6.49 GRIB -- WMO General Regularly-distributed Information in Binary form

Driver short name

GRIB

Driver built-in by default

This driver is built-in by default

GDAL supports GRIB1 (reading) and GRIB2 (reading and writing) format raster data, with support for common coordinate system, georeferencing and other metadata. GRIB format is commonly used for distribution of Meteorological information, and is propagated by the World Meteorological Organization.

The GDAL GRIB driver is based on a modified version of the degrib application which is written primarily by Arthur Taylor of NOAA NWS NDFD (MDL). The degrib application (and the GDAL GRIB driver) are built on the g2clib grib decoding library written primarily by John Huddleston of NOAA NWS NCEP.

GRIB2 files without projection on lon/lat grids have the peculiarity of using longitudes in the [0,360] range and wrapping around the antimeridian as opposed to the usual wrapping around the prime meridian of other raster datasets. Starting with GDAL 3.4.0, when reading such files, a transparent conversion of the longitudes to [-180,180] will be performed and the data will be rewrapped around the prime meridian - the split&swap mode. This behavior can be disabled by setting the *GRIB_ADJUST_LONGITUDE_RANGE* configuration option to *NO*.

There are several encoding schemes for raster data in GRIB format. Most common ones should be supported including PNG encoding. JPEG2000 encoded GRIB files will generally be supported if GDAL is also built with JPEG2000 support via one of the GDAL JPEG2000 drivers.

GRIB files may a be represented in GDAL as having many bands, with some sets of bands representing a time sequence. GRIB bands are represented as Float64 (double precision floating point) regardless of the actual values. GRIB metadata is captured as per-band metadata and used to set band descriptions, similar to this:

```
Description = 100000[Pa] ISBL="Isobaric surface"
  GRIB_UNIT=[gpm]
  GRIB_COMMENT=Geopotential height [gpm]
  GRIB_ELEMENT=HGT
  GRIB_SHORT_NAME=100000-ISBL
  GRIB_REF_TIME=  1201100400 sec UTC
  GRIB_VALID_TIME=  1201104000 sec UTC
  GRIB_FORECAST_SECONDS=3600 sec
```

GRIB2 files may also include an extract of other metadata, such as the identification section, product definition template number (GRIB_PDS_PDTN, octet 8-9), and the product definition template values (GRIB_PDS_TEMPLATE_NUMBERS, octet 10+) as metadata like this:

```
GRIB_DISCIPLINE=0(Meteorological)
GRIB_IDS=CENTER=7(US-NCEP) SUBCENTER=0 MASTER_TABLE=8 LOCAL_TABLE=1 SIGNF_REF_
↪TIME=1(Start_of_Forecast) REF_TIME=2017-10-20T06:00:00Z PROD_STATUS=0(Operational)␣
↪TYPE=1(Forecast)
GRIB_PDS_PDTN=32
GRIB_PDS_TEMPLATE_NUMBERS=5 7 2 0 0 0 0 0 1 0 0 0 0 1 0 31 1 29 67 140 2 0 0 238 217
GRIB_PDS_TEMPLATE_ASSEMBLED_VALUES=5 7 2 0 0 0 0 1 0 1 31 285 17292 2 61145
```

GRIB_DISCIPLINE is the Discipline field of the Section 0 of the message.

GRIB_IDS is the identification section / Section 1 of the message.

GRIB_PDS_TEMPLATE_ASSEMBLED_VALUES use template definitions to assemble several bytes that make a template item into a 16 or 32 bit signed/unsigned integers, whereas GRIB_PDS_TEMPLATE_NUMBERS expose raw bytes

6.49.1 Driver capabilities

Supports Georeferencing

This driver supports georeferencing

Supports CreateCopy()

This driver supports the *GDALDriver::CreateCopy()* operation

Supports VirtualIO

This driver supports *virtual I/O operations (/vsimem/, etc.)*

6.49.2 Configuration options

Configuration options can be specified in command-line tools using the syntax `--config <NAME>=<VALUE>` or using functions such as *CPLSetConfigOption()* (C) or *gdal.config_options* (Python). This paragraph lists the configuration options that can be set to alter the default behavior of the GRIB driver.

- **GRIB_ADJUST_LONGITUDE_RANGE=[YES/NO]:** (GDAL >= 3.4.0) Defaults to `YES`. Convert longitudes from [0, 360] to [-180, 180].
- **GRIB_NORMALIZE_UNITS=[YES/NO]:** Defaults to `YES`. Can be set to NO to avoid GDAL to normalize units to metric. By default (*GRIB_NORMALIZE_UNITS=YES*), temperatures are reported in degree Celsius (°C). With *GRIB_NORMALIZE_UNITS=NO*, they are reported in Kelvin (K).
- **GRIB_RESOURCE_DIR=<path>:** Path to a directory where grib2_*.csv tables are located. If not specified, the *GDAL_DATA* configuration option (or hard coded paths) used for all GDAL resources will be used.

6.49.3 Open options

Open options can be specified in command-line tools using the syntax `-oo <NAME>=<VALUE>` or by providing the appropriate arguments to *GDALOpenEx()* (C) or *gdal.OpenEx* (Python). The following open options are supported:

- **USE_IDX=[YES/NO]:** (GDAL >= 3.4) Defaults to `YES`. Enable automatic reading of external wgrib2 external index files when available. GDAL will look for a *<GRIB>.idx* in the same place as the dataset. These files when combined with careful usage of the API or the CLI tools allow a GRIBv2 file to be opened without reading all the bands. In particular, this allows an orders of magnitude faster extraction of select bands from large GRIBv2 files on remote storage (like NOMADS on AWS S3). In order to avoid unnecessary I/O only the text description of the bands should be accessed as accessing the metadata will require loading of the band header. gdal_translate is supported but gdalinfo is not. This option is ignored when using the multidimensional API (index is then ignored)

6.49.4 GRIB2 write support

GRIB2 write support is available through the CreateCopy() / gdal_translate interface.

Each band of the input dataset is translated as a GRIB2 message, and all of them are concatenated in a single file, conforming to the usual practice.

The input dataset must be georeferenced, and the supported projections are: Geographic Longitude/Latitude, Mercator 1SP/2SP, Transverse Mercator, Polar Stereographic, Lambert Conformal Conic 1SP/2SP, Albers Conic Equal Area and Lambert Azimuthal Equal Area.

A number of creation options are available as detailed in below sections. Those creation options are valid for all bands. But it is possible to override those global settings in a per-band way, by defining creation options that use the same key and are prefixed by BAND_X_ where X is the band number between 1 and the total number of bands. For example BAND_1_PDS_PDTN

6.49.4.1 Product identification and definition

Users are strongly advised to provide necessary information to appropriately fill the Section 0 / "Indicator", Section 1 / "Identification section" and Section 4 / "Product definition section" with the following creation options. Otherwise, GDAL will fill with default values, but readers might have trouble exploiting GRIB2 datasets generating with those defaults. Creation options can be specified in command-line tools using the syntax `-co <NAME>=<VALUE>` or by providing the appropriate arguments to *`GDALCreate()`* (C) or *`Driver.Create`* (Python).

- **DISCIPLINE=<integer>:** sets the Discipline field of Section 0. Valid values are given by Table 0.0:
  - 0: Meteorological Products. Default value
  - 1: Hydrological Products
  - 2: Land Surface Products
  - 3, 4: Space Products
  - 10: Oceanographic Product
- **IDS=value:** String with different elements to fill the fields of the Section 1 / Identification section. The value of that string will typically be retrieved from the GRIB_IDS metadata item of an existing GRIB product. For example "IDS=CENTER=7(US-NCEP) SUBCENTER=0 MASTER_TABLE=8 SIGNF_REF_TIME=1(Start_of_Forecast) REF_TIME=2017-10-20T06:00:00Z PROD_STATUS=0(Operational) TYPE=1(Forecast)". More formally, the format of the string is a list of KEY=VALUE items, with space separator. The accepted keys are CENTER, SUBCENTER, MASTER_TABLE, SIGNF_REF_TIME, REF_TIME, PROD_STATUS and TYPE. Only the numerical part of the value is taken into account (the precision between parenthesis will be ignored). It is possible to use both this IDS creation option and a specific IDS_xxx creation option that will override the potential corresponding xxx key of IDS. For example with the previous example, if both "IDS=CENTER=7(US-NCEP)..." and "IDS_CENTER=8" are define, the actual value used with be 8.
- **IDS_CENTER=<integer>:** Defaults to `255/Missing`. Identification of originating/generating center, according to Table 0.
- **IDS_SUBCENTER=<integer>:** Defaults to `65535/Missing`. Identification of originating/generating center, according to Table C.
- **IDS_MASTER_TABLE=<integer>:** Defaults to `2`. GRIB master tables version number, according to Table 1.0.
- **IDS_SIGNF_REF_TIME=<integer>:** Defaults to `0/Analysis`. Significance of reference time, according to Table 1.2.
- **IDS_REF_TIME=<YYYY-MM-DD[THH:MM:SSZ]>:** Defaults to `1970-01-01T00:00:00Z`. Reference time.

- **IDS_PROD_STATUS=<integer>:** Defaults to `255/Missing`. Production status of processed data, according to Table 1.3.
- **IDS_TYPE=<integer>:** Defaults to `255/Missing`. Type of processed data, according to Table 1.4.
- **PDS_PDTN=<integer>:** Product definition template number, according to Table 4.0. Defaults to 0/Analysis or forecast at a horizontal level or in a horizontal layer at a point in time. If this default template number is used, and none of PDS_TEMPLATE_NUMBERS or PDS_TEMPLATE_ASSEMBLED_VALUES is specified, then a default template definition is also used, with most fields set to Missing.
- **PDS_TEMPLATE_NUMBERS=value:** Product definition template raw numbers. This is a list of byte values (between 0 and 255 each), space separated. The number of values and their semantics depends on the template number specified by PDS_PDTN, and you have to consult the template structures pointed by Table 4.0. It might be easier to use the GRIB_PDS_TEMPLATE_NUMBERS reported by existing GRIB2 products as the value for this item. If the template structure is known by the reading side of the driver, an effort to validate the number of template numbers against the template structure is made (with warnings if more elements than needed are specified, and error if less are specified). It is also possible to define a template that is not or partially implemented by the reading side of the driver.
- **PDS_TEMPLATE_ASSEMBLED_VALUES=value:** Product definition template assembled values. This is a list of values (with the range of signed/unsigned 1, 2 or 4-byte wide integers, depending on the item), space separated. The number of values and their semantics depends on the template number specified by PDS_PDTN, and you have to consult the template structures pointed by Table 4.0. It might be easier to use the GRIB_PDS_TEMPLATE_ASSEMBLED_VALUES reported by existing GRIB2 products as the value for this item. PDS_TEMPLATE_NUMBERS and PDS_TEMPLATE_ASSEMBLED_VALUES are exclusive. To use this creation option, the template structure must be known by the reading side of the driver.

6.49.4.2 Data encoding

In GRIB2, a number of data encoding schemes exist (see Section 5 / "Data representation section"). By default, GDAL will select an appropriate data encoding that will preserve the range of input data. with the *DATA_ENCODING*, *NBITS*, *DECIMAL_SCALE_FACTOR*, *JPEG2000_DRIVER*, *COMPRESSION_RATIO* and *SPATIAL_DIFFERENCING_ORDER* creation options.

Users can override those defaults with the following creation options are:

- **DATA_ENCODING=[AUTO/SIMPLE_PACKING/COMPLEX_PACKING/IEEE_FLOATING_POINT/PNG/JPEG2000]:** Defaults to `AUTO`. Choice of the Data representation template number.
  - In AUTO mode, COMPLEX_PACKING is selected if input band has a nodata value. Otherwise if input band datatype is Float32 or Float64, IEEE_FLOATING_POINT is selected. Otherwise SIMPLE_PACKING is selected.
  - SIMPLE_PACKING: use integer representation internally, with offset and decimal and/or binary scaling. So can be used for any datatype.
  - COMPLEX_PACKING: evolution of SIMPLE_PACKING with nodata handling. By default, a non-spatial differencing encoding is used, but if SPATIAL_DIFFERENCING_ORDER=1 or 2, complex packing with spatial differencing is used
  - IEEE_FLOATING_POINT: store values as IEEE-754 single or double precision numbers.
  - PNG: uses the same preparation steps as SIMPLE_PACKING but with PNG encoding of the integer values.
  - JPEG2000: uses the same preparation steps as SIMPLE_PACKING but with JPEG2000 encoding of the integer values.
- **NBITS=1-31:** Bit width for each sample value. Might be only loosely honored by some *DATA_ENCODING*. If not specified, the bit width is computed automatically from the range of input values for integral data types, or default to 8 for Float32/Float64.

- **DECIMAL_SCALE_FACTOR=<integer>:** Defaults to 0. Input values are multiplied by 10^DECIMAL_SCALE_FACTOR before integer encoding (and automatically divised by this value at decoding, so this only affect precision). For example, if the type of the data is a temperature, with floating point data type, DECIMAL_SCALE_FACTOR=1 can be used to specify that the data has a precision of 1/10 of degree. The default is 0 (no premultiplication)
- **SPATIAL_DIFFERENCING_ORDER=[0/1/2]:** Defaults to 0. Only used for *DATA_ENCODING=COMPLEX_PACKING*. Defines the order of the spatial differencing. 0 means that the values are encoded independently, 1 means that the difference of consecutive values is encoded and 2 means that the difference of the difference of consecutive values is encoded.
- **COMPRESSION_RATIO=1-100:** Defaults to 1. Defaults to 1 for lossless JPEG2000 encoding. Only used for JPEG2000 encoding. If a value greater than 1 is specified, lossy JPEG2000 compression is used. The value indicates the desired compression factor with respected to uncompressed data. For example a value of 10 means that the desired JPEG2000 codestream should be 10 times smaller than the corresponding uncompressed file (with NBITS bits per pixel).
- **JPEG2000_DRIVER=[JP2KAK/JP2OPENJPEG/JPEG2000/JP2ECW]:** (possible values depend on the actually available JPEG2000 driver in the GDAL build). To specify which JPEG2000 driver should be used. If not specified, drivers are searched in the order given in the enumeration.

6.49.4.3 Data units

Internally GRIB stores values in the units of the international system (ie Metric system). So temperatures must be stored as Kelvin degrees. But on the reading side of the driver, fields with temperatures are exposed in Celsius degrees (unless the *GRIB_NORMALIZE_UNITS* configuration option is set to NO). For consistency, the writing side of the driver also assumed that temperature (detected if the first value of a product definition template, ie the *Parameter category* is 0=Temperature) values in the input dataset will be in Celsius degrees, and will automatically offset them to Kelvin degrees. It is possible to control that behavior using the *INPUT_UNIT* creation option:

- **INPUT_UNIT=[C/K]:** Defaults to C. Used to specify temperature units when writing: C (for Celsius) or K (for Kelvin).

6.49.4.4 GRIB2 to GRIB2 conversions

If GRIB2 to GRIB2 translation is done with gdal_translate (or CreateCopy()), the GRIB_DISCIPLINE, GRIB_IDS, GRIB_PDS_PDTN and GRIB_PDS_TEMPLATE_NUMBERS metadata items of the bands of the source dataset are used by default (unless creation options override them).

DECIMAL_SCALE_FACTOR and NBITS will also be attempted to be retrieved from the GRIB special metadata domain.

6.49.4.5 Examples

```
gdal_translate in.tif out.grb2 -of GRIB \
    -co "IDS=CENTER=8(US-NWSTG) SIGNF_REF_TIME=1(Start_of_Forecast) REF_TIME=2008-02-
↪21T17:00:00Z PROD_STATUS=0(Operational) TYPE=1(Forecast)" \
    -co "PDS_PDTN=8" \
    -co "PDS_TEMPLATE_ASSEMBLED_VALUES=0 5 2 0 0 255 255 1 43 1 0 0 255 -1 -2147483647␣
↪2008 2 23 12 0 0 1 0 3 255 1 12 1 0"
```

6.49.6 Credits

Support for GRIB2 write capabilities has been funded by Meteorological Service of Canada.

6.50 GS7BG -- Golden Software Surfer 7 Binary Grid File Format

Driver short name

GS7BG

Driver built-in by default

This driver is built-in by default

This is the binary (non-human-readable) version of one of the raster formats used by Golden Software products (such as the Surfer series). This format differs from the *GSBG -- Golden Software Binary Grid File Format* format (also known as Surfer 6 binary grid format), it is more complicated and flexible.

NOTE: Implemented as gs7bgdataset.cpp.

6.50.1 Driver capabilities

Supports CreateCopy()

This driver supports the `GDALDriver::CreateCopy()` operation

Supports Create()

This driver supports the `GDALDriver::Create()` operation

Supports Georeferencing

This driver supports georeferencing

Supports VirtualIO

This driver supports *virtual I/O operations (/vsimem/, etc.)*

6.51 GSAG -- Golden Software ASCII Grid File Format

Driver short name

GSAG

Driver built-in by default

This driver is built-in by default

This is the ASCII-based (human-readable) version of one of the raster formats used by Golden Software products (such as the Surfer series). This format is supported for both reading and writing (copy mode only). Currently the associated formats for color, metadata, and shapes are not supported.

NOTE: Implemented as gsagdataset.cpp.

6.51.1 Driver capabilities

Supports CreateCopy()

This driver supports the `GDALDriver::CreateCopy()` operation

Supports Georeferencing

This driver supports georeferencing

Supports VirtualIO

This driver supports *virtual I/O operations (/vsimem/, etc.)*

6.52 GSBG -- Golden Software Binary Grid File Format

Driver short name

GSBG

Driver built-in by default

This driver is built-in by default

This is the binary (non-human-readable) version of one of the raster formats used by Golden Software products (such as the Surfer series).

Like the ASCII version, this format is supported for both reading and writing (including create, delete, and copy). Currently the associated formats for color, metadata, and shapes are not supported.

Surfer 8 uses a fixed nodata value at 1.701410009187828e+38. When writing a GSBG dataset, GDAL remaps the user-specified input nodata value to 1.701410009187828e+38.

NOTE: Implemented as gsbgdataset.cpp.

6.52.1 Driver capabilities

Supports CreateCopy()

This driver supports the *GDALDriver::CreateCopy()* operation

Supports Create()

This driver supports the *GDALDriver::Create()* operation

Supports Georeferencing

This driver supports georeferencing

Supports VirtualIO

This driver supports *virtual I/O operations (/vsimem/, etc.)*

6.53 GSC -- GSC Geogrid

Driver short name

GSC

Driver built-in by default

This driver is built-in by default

NOTE: Implemented as gscdataset.cpp.

6.53.1 Driver capabilities

Supports VirtualIO

This driver supports *virtual I/O operations (/vsimem/, etc.)*

6.54 GDALG: GDAL Streamed Algorithm

Added in version 3.11.

Driver short name

GDALG

Driver built-in by default

This driver is built-in by default

Note

GDALG is the contraction of GDAL and ALGorithm.

This is a read-only driver that reads a JSON file containing an invocation of the *gdal command line interface*, that results in a on-the-fly / streamed raster dataset when used as an input to *GDALOpenEx()*, or anywhere else in GDAL where a raster input dataset is expected. GDALG files are conceptually close to *VRT (Virtual) files*, although the implementation is substantially different.

The subset of commands of **gdal** that can generate such streamed datasets indicate support for writing `GDALG` in the `--help` description for `--output-format`. This includes *gdal raster pipeline*, *gdal raster mosaic* or *gdal raster stack*.

It is recommended that GDALG files use the `.gdalg.json` extension.

The JSON document must include a `type` member with the value `gdal_streamed_alg`, and a `command_line` member, which is very close to the one that would be used to generate a materialized dataset, but using the `stream` output format.

```
{
    "type": "gdal_streamed_alg",
    "command_line": "gdal raster mosaic in1.tif in2.tif --output-format stream streamed_
↪dataset"
}
```

If such file is saved as `mosaic.gdalg.json`, it can be for example read with `gdal raster info mosaic.gdalg.json`.

In the case of a *gdal raster pipeline*, the final `write` step can be omitted.

```
{
    "type": "gdal_streamed_alg",
    "command_line": "gdal raster pipeline ! read in.tif ! reproject --dst-crs=EPSG:32632"
}
```

An optional `relative_paths_relative_to_this_file` boolean member defaults to `true`, to indicate that relative input filenames in the command line should be interpreted as relative to the location of the `.gdalg.json` file. If setting this member to `false`, they will be interpreted as being relative to the current working directory.

`.gdalg.json` files can be validated against the following JSON schema gdalg.schema.json

This driver has also vector capabilities as detailed in *GDALG: GDAL Streamed Algorithm*.

6.54.1 Driver capabilities

Supports Georeferencing

This driver supports georeferencing

6.55 GTA - Generic Tagged Arrays

Driver short name

GTA

Build dependencies

libgta

GDAL can read and write GTA data files through the libgta library.

GTA is a file format that can store any kind of multidimensional array data, allows generic manipulations of array data, and allows easy conversion to and from other file formats.

6.55.1 Driver capabilities

Supports CreateCopy()

This driver supports the *GDALDriver::CreateCopy()* operation

Supports Georeferencing

This driver supports georeferencing

6.55.2 Creation options

Creation options can be specified in command-line tools using the syntax `-co <NAME>=<VALUE>` or by providing the appropriate arguments to *GDALCreate()* (C) or *Driver.Create* (Python). The following creation options are supported:

- **COMPRESS=[NONE/BZIP2/XZ/ZLIB/ZLIB1/ZLIB2/ZLIB3/ZLIB4/ZLIB5/ZLIB6/ZLIB7/ZLIB8/ZLIB9]:** Defaults to `NONE`. Set the GTA compression method.

6.56 GTI -- GDAL Raster Tile Index

Added in version 3.9.

Driver short name

GTI

Driver built-in by default

This driver is built-in by default

6.56.1 Introduction

The GTI driver is a driver that allows to handle catalogs with a large number of raster files (called "tiles" in the rest of this document, even if a regular tiling is not required by the driver), and build a virtual mosaic from them. Each tile may be in any GDAL supported raster format, and be a file stored on a regular filesystem, or any GDAL supported virtual filesystem (for raster drivers that support such files).

This driver offers similar functionality as the *VRT* driver with the following main differences:

- The tiles are listed as features of any GDAL supported vector format. Use of formats with efficient spatial filtering is recommended, such as *GeoPackage*, *FlatGeoBuf* or *PostGIS*. The GTI driver can thus use a larger number of tiles than the VRT driver (hundreds of thousands or more), provided the underlying vector format is efficient.
- The tiles may have different SRS. The GTI driver is capable of on-the-fly reprojection
- The GTI driver offers control on the order in which tiles are composited, when they overlap (z-order)
- The GTI driver honours the mask/alpha band when compositing together overlapping tiles.
- Contrary to the VRT driver, the GTI driver does not enable to alter characteristics of referenced tiles, such as their georeferencing, nodata value, etc. If such behavior is desired, the tiles must be for example wrapped individually in a VRT file (or *vrt://* connection string) before being referenced in the GTI index.

6.56.2 Connection strings

The GTI driver accepts different types of connection strings:

- a vector file in GeoPackage format with a `.gti.gpkg` extension, or in FlatGeoBuf format with a `.gti.fgb` extension, meeting the minimum requirements for a GTI compatible tile index, detailed later.

  For example: `tileindex.gti.gpkg`

  Starting with GDAL 3.10, specifying the `-if GTI` option to command line utilities accepting it, or `GTI` as the only value of the `papszAllowedDrivers` of *GDALOpenEx()*, also forces the driver to recognize the passed filename if its extension is just `.gpkg` or `.fgb`.

- any vector file in a GDAL supported format, with its filename (or connection string prefixed with `GTI:`

  For example: `GTI:tileindex.shp` or `GTI:PG:database=my_db schema=tileindex`

- a XML file, following the below GTI XML format, generally with the recommended `.gti` extension, referencing a vector file. Using such XML file may be more practical for tile indexes not stored in a file, or if some additional metadata must be defined at the dataset or band level of the virtual mosaic.

  For example: `tileindex.gti`

6.56.3 STAC GeoParquet support

Added in version 3.10.

The driver can support STAC GeoParquet catalogs, provided GDAL is built with *(Geo)Parquet* support. It can make use of fields (`proj:code`, `proj:epsg`, `proj:wkt2`, or `proj:projson`) and `proj:transform` from the Projection Extension Specification, to correctly infer the appropriate projection and resolution.

Since GDAL 3.13, program *gdal raster index* can generate such catalogs with the `--profile STAC-GeoParquet` option.

Example of a valid connection string: `GTI:/vsicurl/https://github.com/stac-utils/stac-geoparquet/raw/main/tests/data/naip.parquet`

6.56.4 Tile index requirements

The minimum requirements for a GTI compatible tile index is to be a vector format supported by GDAL, with a geometry column storing polygons with the extent of the tiles, and an attribute field of type string, storing the path to each tile. The default name for this attribute field is `location`. If relative filenames are stored in the tile index, they are considered to be relative to the path of the tile index.

In addition, for formats that can store layer metadata (GeoPackage, FlatGeoBuf, PostGIS, ...), the following layer metadata items may be set:

- `RESX=<float>` and `RESY=<float>`: resolution along X and Y axis, in SRS units / pixel.

  Setting those metadata items is recommended, otherwise the driver will try to open one of the tiles referenced in the tile index, and use its resolution as the resolution for the mosaic.

- `BAND_COUNT=<int>`: number of bands of the virtual mosaic. The tiles stored in an index should generally have the same number of bands.

  Setting that metadata item is recommended, otherwise the driver will try to open one of the tiles referenced in the tile index, and use it as the number of bands for the mosaic.

  A mix of tiles with N and N+1 bands is allowed, provided that the color interpretation of the (N+1)th band is alpha. The N+1 value must be written as the band count in that situation.

  If tiles contains a single band with a color table, and that the color table may differ among tiles, BAND_COUNT should be set to 3 (resp. 4) to perform expansion to Red, Green, Blue components (resp. Red, Green, Blue, Alpha). If the color table is identical between the tiles, and it is desired to preserve it, the VRRTI XML file format may be used to include the ColorTable element.

- `DATA_TYPE=<val>`: data type of the tiles of the tile index `Byte`, `Int8`, `UInt16`, `Int16`, `UInt32`, `Int32`, `UInt64`, `Int64`, `Float32`, `Float64`, `CInt16`, `CInt32`, `CFloat32` or `CFloat64`

  Setting that metadata item is recommended, otherwise the driver will try to open one of the tiles referenced in the tile index, and use it as the data type for the mosaic.

- `NODATA=<val>[,<val]...`: nodata value of the bands of the virtual mosaic.

  Note that source tiles may have or may not have a nodata value themselves, and it may be different than the nodata value of the virtual mosaic.

- `MINX=<float>`, `MINY=<float>`, `MAXX=<float>` and `MAXY=<float>`: defines the extent of the virtual mosaic.

  For vector formats that have efficient retrieval of the layer extent, setting those items is not needed.

- `GEOTRANSFORM=<gt0>,<gt1>,<gt2>,<gt3>,<gt4>,<gt5>`: defines the GeoTransform. Used together with `XSIZE` and `YSIZE`, this is an alternate way of defining the extent and resolution os the virtual mosaic.

  It is not necessary to define this item if `RESX=` and `RESY` are set (potentially accompanied with `MINX`, `MINY`, `MAXX` and `MAXY`)

- XSIZE=<int>, YSIZE=<int>: size of the virtual mosaic in pixel.
- COLOR_INTERPRETATION=<val>[,<val]...: color interpretation of the bands of the mosaic. Possible values are red, green, blue, alpha, undefined
- SRS=<string>: specifies the SRS of the virtual mosaic, using any value supported by the *OGRSpatialReference::SetFromUserInput()* call, which includes EPSG Projected, Geographic or Compound CRS (i.e. EPSG:4296), a well known text (WKT) CRS definition, PROJ.4 declarations, etc.

  It is not necessary to define this element if the virtual mosaic SRS is recorded as the SRS of the vector layer of the tile index.

  When SRS is set and the vector layer already has a different SRS, a warning is emitted unless SRS_BEHAVIOR is also set. See SRS_BEHAVIOR below.
- SRS_BEHAVIOR=OVERRIDE|REPROJECT: controls how the SRS parameter interacts with an existing SRS on the vector layer.
  - OVERRIDE: use the specified SRS as the dataset SRS without reprojecting tile coordinates. Use this when the layer's SRS metadata is missing or incorrect and you want to correct it.
  - REPROJECT: reproject tile coordinates from the layer's native SRS to the specified SRS on the fly, including transforming spatial filters applied during raster reads. Use this when you want the virtual mosaic in a different projection than the tile index layer.

  If SRS is set and differs from the vector layer's SRS and SRS_BEHAVIOR is not specified, a warning is emitted. If the vector layer has no SRS, the specified SRS is used silently regardless of this option.

  > **Note**
  >
  > For on-the-fly reprojection of the whole GTI mosaic output, wrapping the GTI file in a warped VRT (e.g. via gdal raster reproject) is an alternative that does not require SRS_BEHAVIOR.

- LOCATION_FIELD=<string>: name of the field where the tile location is stored. Defaults to location.
- SORT_FIELD=<string>: name of a field to use to control the order in which tiles are composited, when they overlap (z-order). That field may be of type String, Integer, Integer64, Date or DateTime. By default, the higher the value in that field, the last the corresponding tile will be rendered in the virtual mosaic (unless SORT_FIELD_ASC=NO is set)
- SORT_FIELD_ASC=YES|NO: whether the values in SORT_FIELD should be sorted in ascending or descending order. Defaults to YES (ascending)
- BLOCKXSIZE=<int> and BLOCKYSIZE=<int>: Block size of bands of the virtual mosaic. Defaults to 256x256.
- MASK_BAND=YES|NO: whether a dataset-level mask band should be exposed. Defaults to NO.
- RESAMPLING=<val>: Resampling method to use for on-the-fly reprojection, or rendering of tiles whose origin coordinates are not at an offset multiple of the resolution of the mosaic compared to the origin of the mosaic. In that later case, RESAMPLING is only taken into account when requesting pixels with the default nearest resampling mode.

  Possible values: nearest, cubic, cubicspline, lanczos, average, rms, gauss

  Defaults to nearest
- BAND_<number>_OFFSET=<val> where number is an integer index starting at 1.

  Additive offset to apply to the raw numbers of the band.
- BAND_<number>_SCALE=<val> where number is an integer index starting at 1.

Multiplicative factor to apply to the raw numbers of the band.

- BAND_<number>_UNITTYPE=<val> where number is an integer index starting at 1.

  Unit of the band.

- OVERVIEW_<idx>_DATASET=<string>. See *Overviews as metadata items of a GDAL vector layer*
- OVERVIEW_<idx>_LAYER=<string>. See *Overviews as metadata items of a GDAL vector layer*
- OVERVIEW_<idx>_OPEN_OPTIONS=<key1=value1>[,key2=value2]... . See *Overviews as metadata items of a GDAL vector layer*
- OVERVIEW_<idx>_FACTOR=<int>. See *Overviews as metadata items of a GDAL vector layer*
- INTERLEAVE=<val> (starting with GDAL 3.13) where <val> can be PIXEL or BAND specifies how pixels belonging to multiple bands are grouped together. This setting affects performance, both how external code accesses pixel values, and internal operation of the driver. When using *gdal driver gti create*, the value is automatically set to match interleave mode among the input sources. Accessing sources whose interleave mode differs from the exposed value may result in reduced performance. See *Multiband pixel organization (INTERLEAVE metadata item)* for more details.

All overviews *must* have exactly the same extent as the full resolution virtual mosaic. The GTI driver does not check that, and if that condition is not met, subsampled pixel request will lead to incorrect result.

They also must be listed by decreasing size with increasing overview index.

In addition to those layer metadata items, the dataset-level metadata item TILE_INDEX_LAYER may be set to indicate, for dataset with multiple layers, which one should be used as the tile index layer.

Since GDAL 3.12, the dataset-level metadata item TILE_INDEX_SQL can be used to specify a SQL request that returns a result set, in addition to or in replacement to TILE_INDEX_LAYER. The dataset-level metadata item TILE_INDEX_SPATIAL_SQL can be used as a complement to TILE_INDEX_SQL for a SQL request that contains placeholders {XMIN}, {YMIN}, {XMAX}, {YMAX} that are substituted at runtime with the coordinates of the requested area of interest.

For example, given a tileindex table with fields location, tile_id and version, where several features may have the same tile_id value, but with different version, the following SQL request (to be used for example in a Spatialite or GeoPackage database) can be use to always select tiles with the latest version:

```
WITH target_version AS (SELECT tile_id,max(version) AS version FROM tileindex GROUP BY␣
↪tile_id)
SELECT * FROM tileindex INNER JOIN target_version
ON target_version.tile_id=tileindex.tile_id AND target_version.version=tileindex.version
```

And in a Spatialite database, the following can be used as the TILE_INDEX_SPATIAL_SQL:

```
WITH target_version AS (SELECT tile_id,max(version) AS version FROM tileindex GROUP BY␣
↪tile_id)
SELECT * FROM tileindex INNER JOIN target_version
ON target_version.tile_id=tileindex.tile_id AND target_version.version=tileindex.version
INNER JOIN idx_tileindex_geometry ON tileindex.ogc_fid = idx_tileindex_geometry.pkid
WHERE idx_tileindex_geometry.xmin <= {XMAX} and idx_tileindex_geometry.ymin <= {YMAX} AND
      idx_tileindex_geometry.xmax >= {XMIN} and idx_tileindex_geometry.ymax >= {YMIN}
```

Alternatively to setting those metadata items individually, the corresponding information can be grouped together in a GTI XML document, attached in the xml:GTI metadata domain of the layer (for drivers that support alternate metadata domains such as GeoPackage)

6.56.5 GTI XML format

A XML schema of the GDAL GTI format (gdaltileindex.xsd) is available.

The following artificial example contains all potential elements and attributes. A number of them have similar name and same semantics as layer metadata items mentioned in the previous section.

```
<GDALTileIndexDataset>
    <IndexDataset>PG:dbname=my_db</IndexDataset>   <!-- required for standalone XML GTI␣
↪files. Ignored if embedded in the xml:GTI metadata domain of the layer  -->
    <IndexLayer>my_layer</IndexLayer>              <!-- optional, but required if there␣
↪are multiple layers in IndexDataset -->
    <SQL>SQL statement</SQL>                       <!-- optional (since 3.12).␣
↪Complement or replacement to IndexLayer -->
    <SpatialSQL>SQL statement</SpatialSQL>         <!-- optional (since 3.12).␣
↪Complement to SQL -->
    <Filter>pub_date >= '2023/12/01'</Filter>      <!-- optional -->
    <SortField>pub_date</SortField>                <!-- optional -->
    <SortFieldAsc>true</SortFieldAsc>              <!-- optional -->
    <SRS>EPSG:4326</SRS>                           <!-- optional -->
    <ResX>60</ResX>                                <!-- optional, but recommended -->
    <ResY>60</ResY>                                <!-- optional, but recommended -->
    <MinX>0</MinX>                                 <!-- optional -->
    <MinY>1</MinY>                                 <!-- optional -->
    <MaxX>2</MaxX>                                 <!-- optional -->
    <MaxY>3</MaxY>                                 <!-- optional -->
    <GeoTransform>2,1,0,49,0,-1</GeoTransform>     <!-- optional -->
    <XSize>2048</XSize>                            <!-- optional -->
    <YSize>1024</YSize>                            <!-- optional -->
    <BlockXSize>256</BlockXSize>                   <!-- optional -->
    <BlockYSize>256</BlockYSize>                   <!-- optional -->
    <Resampling>Cubic</Resampling>                 <!-- optional -->
    <BandCount>1</BandCount>                       <!-- optional, not needed if Band␣
↪elements are defined -->

    <!-- Band is optional, but recommended. Repeated as many times as there are bands -->
    <!-- The "band" attribute is required -->
    <!-- The "dataType" attribute is optional, but recommended -->
    <Band band="1" dataType="Byte">
        <Description>my band</Description>         <!-- optional -->
        <Offset>2</Offset>                         <!-- optional -->
        <Scale>3</Scale>                           <!-- optional -->

        <Dataset>another.tif</Dataset>
        <! -- The reduction factor is relative to the size of the full
              resolution layer of the designated dataset,
              and *not* relative to the size of the full
              resolution layer of the GTI dataset.
              It is also possible to select a particular overview by
              using the OVERVIEW_LEVEL open option.
        -->
        <Factor>4</Factor>
    </Overview>
    <Overview>                                     <!-- optional -->
        <!-- 5th overview level. -->
        <Dataset>another.tif</Dataset>
```

(continues on next page)

(continued from previous page)

```
        <! -- Use the overview level of index 2 -->
         <OpenOptions>
              <OOI key="OVERVIEW_LEVEL">2</OOI>
         </OpenOptions>
    </Overview>
    <Overview>                                      <!-- optional -->
        <!-- Last overview level points to another GTI dataset -->
        <Dataset>other.gti.gpkg</Dataset>
        <Layer>other_layer</Layer>                  <!-- optional -->
        <OpenOptions>                               <!-- optional -->
            <OOI key="MINX">2</OOI>
            <OOI key="MINY">49</OOI>
            <OOI key="MAXX">3</OOI>
            <OOI key="MAXY">50</OOI>
        </OpenOptions>
    </Overview>

    <Interleave>Band|Pixel</Interleave>             <!-- optional -->

</GDALTileIndexDataset>
```

At the GDALTileIndexDataset level, the elements specific to GTI XML are:

- `Filter`: value of a SQL WHERE clause, used to select a subset of the features of the index.
- `BlockXSize` / `BlockYSize`: dimension of the block size of bands. Defaults to 256x256
- `Metadata`: defines dataset-level metadata. You can refer to the documentation of the *VRT* driver for its syntax.

At the Band level, the elements specific to GTI XML are: Description, Offset, Scale, UnitType, ColorTable, CategoryNames, GDALRasterAttributeTable, Metadata. You can refer to the documentation of the *VRT* driver for their syntax and semantics.

6.56.6 How to build a GTI compatible index ?

The *gdaltindex* program, or starting with GDAL 3.11, *gdal driver gti create*, may be used to generate both a vector tile index, and optionally a wrapping .gti XML file.

A GTI compatible index may also be created by any programmatic means, provided the above format specifications are met.

6.56.7 Open options

Open options can be specified in command-line tools using the syntax `-oo <NAME>=<VALUE>` or by providing the appropriate arguments to *`GDALOpenEx()`* (C) or *`gdal.OpenEx`* (Python). The following open options are available. Most of them can be also defined as layer metadata items or in the .gti XML file

- **LAYER=<string>:** For dataset with multiple layers, indicates which one should be used as the tile index layer. Same role as the TILE_INDEX_LAYER dataset level metadata item
- **SQL=<string>:** (GDAL >= 3.12) SQL request that returns a result set, in addition to or in replacement to LAYER. Same role as the TILE_INDEX_SQL dataset level metadata item.
- **SPATIAL_SQL=<string>:** (GDAL >= 3.12) SQL request that contains placeholders `{XMIN}`, `{YMIN}`, `{XMAX}`, `{YMAX}` that are substituted at runtime with the coordinates of the requested area of interest. Complement to *`SQL`*. Same role as the TILE_INDEX_SPATIAL_SQL dataset level metadata item.
- **LOCATION_FIELD=<string>:** Defaults to `location`. Name of the field where the tile location is stored.

- **SORT_FIELD=<string>:** Name of a field to use to control the order in which tiles are composited, when they overlap (z-order). That field may be of type String, Integer, Integer64, Date or DateTime. By default, the higher the value in that field, the last the corresponding tile will be rendered in the virtual mosaic (unless SORT_FIELD_ASC=NO is set)
- **SORT_FIELD_ASC=[YES/NO]:** Defaults to `YES`. Whether the values in SORT_FIELD should be sorted in ascending or descending order
- **FILTER=<string>:** Value of a SQL WHERE clause, used to select a subset of the features of the index.
- **RESX=<float>:** Resolution along X axis in SRS units / pixel.
- **RESY=<float>:** Resolution along Y axis in SRS units / pixel.
- **SRS=<string>:** Specifies the Spatial Reference System in one of the formats supported by *`OGRSpatialReference::SetFromUserInput()`*. When set and the vector layer already has a different SRS, see `SRS_BEHAVIOR`.
- **SRS_BEHAVIOR=[OVERRIDE/REPROJECT]:** Controls how `SRS` interacts with an existing SRS on the vector layer. `OVERRIDE` sets the dataset SRS without reprojecting tile coordinates. `REPROJECT` reprojects tile coordinates from the layer's native SRS to the specified SRS on the fly. If `SRS` is set and differs from the layer's SRS and this option is not specified, a warning is emitted.
- **MINX=<float>:** Minimum X value for the virtual mosaic extent
- **MINY=<float>:** Minimum Y value for the virtual mosaic extent
- **MAXX=<float>:** Maximum X value for the virtual mosaic extent
- **MAXY=<float>:** Maximum Y value for the virtual mosaic extent
- **WARPING_MEMORY_SIZE.=<string>:** (GDAL >= 3.12.3) Defaults to `64MB`. Set the amount of memory that the warp API is allowed to use for caching when on-the-fly reprojection occurs. The value can be specified either as a fixed amount of memory (e.g. `200MB`, `1G`) or as a percentage of usable RAM (`10%`). Note that, in case of multi-threaded optimizations described in the paragraph below, the value applies for each warped source.

6.56.8 Overviews

By default the minimal configuration of a GTI dataset does not expose explicit overviews. But downsampled pixel requests to a GTI dataset may use overviews of the source tiles referenced by the GTI dataset when they exist.

It is possible to provide explicit overview levels that the GTI dataset will expose to external users (and of course use for downsampled pixel requests). This can be done through one or several `<Overview>` elements in the GTI XML format, or by using specific layer metadata keys starting with `OVERVIEW_{idx}` when using a vector dataset as the GTI dataset.

In both cases, each added overview level may be: - a downsampled version of the main GTI dataset - another GTI dataset, at its full resolution or at a subsampled one - any other GDAL recognized raster file, at its full resolution or at a subsampled one.

The order of declaration may matter. Overview levels directly or indirectly specified by later XML or metadata items are only added if their size is smaller than the previously added overview.

6.56.8.1 Overviews in XML

The general syntax for each overview level is:

```
<Overview>
    <Dataset>other.gti.gpkg</Dataset>
    <Layer>other_layer</Layer>
    <Factor>numeric_value_larger_than_one>
    <OpenOptions>
```

(continues on next page)

(continued from previous page)

```
        <OOI key="key">value</OOI>
    </OpenOptions>
</Overview>
```

All elements are optional, but at least one of `Dataset`, `Layer` or `Factor` must be specific. Note also that at most one of those child elements is allowed per `<Overview>` element. So typically if several levels from a same dataset are needed, one `<Overview>` element per level must be specified.

Example 1

This example uses the tile index of the IndexDataset and IndexLayer elements, with all source tiles downsampled by a factor of 2.

```
<Overview>
    <Factor>2</Factor>
</Overview>
```

Example 2

This example uses a GeoTIFF file, and all its potential overviews, as overviews of the GTI dataset

```
<Overview>
    <Dataset>some.tif</Dataset>
</Overview>
```

Example 3

This example uses the overview level of a GeoTIFF file whose dimensions are at least four times smaller than the full resolution layer of `another.tif`.

```
<Overview>
    <Dataset>another.tif</Dataset>
    <Factor>4</Factor>
</Overview>
```

Example 4

This example uses the overview of index 2 of a GeoTIFF file (so given that overview indexing starts at 0, and the full resolution layer is not including in this numbering, this is the 4th layer in size of the file)

```
<Overview>
    <Dataset>another.tif</Dataset>
     <OpenOptions>
          <OOI key="OVERVIEW_LEVEL">2</OOI>
     </OpenOptions>
</Overview>
```

Example 5

This example points to another GTI dataset, with an explicit layer name, and by adjusting its extent to the one of the main GTI dataset (assuming such extent is 2,49,3,50).

```
<Overview>
    <Dataset>other.gti.gpkg</Dataset>
    <Layer>other_layer</Layer>
    <OpenOptions>
        <OOI key="MINX">2</OOI>
        <OOI key="MINY">49</OOI>
        <OOI key="MAXX">3</OOI>
        <OOI key="MAXY">50</OOI>
    </OpenOptions>
</Overview>
```

6.56.8.2 Overviews as metadata items of a GDAL vector layer

The recognized metadata items all start with `OVERVIEW_<idx>_` where idx is an integer index (starting at 0 since GDAL 3.9.2, starting at 1 in previous versions

- `OVERVIEW_<idx>_DATASET=<string>`

  Name of the dataset to use as an overview level. This may be a raster dataset (for example a GeoTIFF file, or another GTI dataset). This may also be a vector dataset with a GTI compatible layer, potentially specified with `OVERVIEW_<idx>_LAYER`.

  Starting with GDAL 3.9.2, overviews of `OVERVIEW_<idx>_DATASET=<string>` are also automatically added, unless `OVERVIEW_<idx>_OPEN_OPTIONS=OVERVIEW_LEVEL=NONE` is specified (or, since 3.13, `OVERVIEW_<idx>_FACTOR=1`)

- `OVERVIEW_<idx>_OPEN_OPTIONS=<key1=value1>[,key2=value2]...`

  Open options(s) to use to open `OVERVIEW_<idx>_DATASET`.

- `OVERVIEW_<idx>_LAYER=<string>`

  Only taken into account if `OVERVIEW_<idx>_DATASET=<string>` is not specified, or points to a GTI dataset.

  Name of the vector layer to use as an overview level, assuming `OVERVIEW_<idx>_DATASET` points to a vector dataset. `OVERVIEW_<idx>_DATASET` may also not be specified, in which case the vector dataset of the full resolution virtual mosaic is used.

- `OVERVIEW_<idx>_FACTOR=<int>`

  Sub-sampling factor, greater or equal to 1 (1 accepted only since GDAL 3.13)

  Before GDAL 3.13, was only taken into account if `OVERVIEW_<idx>_DATASET=<string>` was not not specified, or pointed to a GTI dataset. Since GDAL 3.13, `OVERVIEW_<idx>_FACTOR` is also accepted on any valid `OVERVIEW_<idx>_DATASET`.

  If `OVERVIEW_<idx>_DATASET` and `OVERVIEW_<idx>_LAYER` are not specified, then all tiles of the full resolution virtual mosaic are used, with the specified sub-sampling factor (it is recommended, but not required, that those tiles do have a corresponding overview). `OVERVIEW_<idx>_DATASET` and/or `OVERVIEW_<idx>_LAYER` may also be specified to point to another tile index.

Example 6

This example is the equivalent of all the examples of the *Overviews in XML* section.

```
# Use the sources of the current GTI file, downsampled by a factor of 2
OVERVIEW_0_FACTOR=2

# Use the full resolution of some.tif and all its potential overviews.
OVERVIEW_1_DATASET=some.tif

# Use the first overview level of another.tif that is at least smaller
# than the dimensions of its full resolution layer divided by a factor of 4.
OVERVIEW_2_DATASET=another.tif
OVERVIEW_2_FACTOR=4

# Use the overview of index 2 from another.tif
OVERVIEW_3_DATASET=another.tif
OVERVIEW_3_OPEN_OPTIONS=OVERVIEW_LEVEL=2

# Use 'other_layer' of 'other.gti.gpkg' and adjust its extent to the one
# of the main GTI dataset (assuming such extent is 2,49,3,50).
OVERVIEW_4_DATASET=other.gti.gpkg
OVERVIEW_4_LAYER=layer
OVERVIEW_4_OPEN_OPTIONS=MINX=2,MINY=49,MAXX=3,MAXY=50
```

6.56.9 Multi-threading optimizations

Starting with GDAL 3.10, the *NUM_THREADS* open option can be set to control specifically the multi-threading of GTI datasets. It defaults to `ALL_CPUS`, and when set, overrides *GDAL_NUM_THREADS* or *GTI_NUM_THREADS*. It applies to band-level and dataset-level RasterIO(), if more than 1 million pixels are requested and if the mosaic is made of only non-overlapping tiles.

- **NUM_THREADS=[integer/ALL_CPUS]:** Defaults to `ALL_CPUS`. Determines the number of threads used when an operation reads from multiple sources.

This can also be specified globally with the *GTI_NUM_THREADS* configuration option.

- **GTI_NUM_THREADS=[integer/ALL_CPUS]:** Defaults to `ALL_CPUS`. Determines the number of threads used when an operation reads from multiple sources.

Note that the number of threads actually used is also limited by the *GDAL_MAX_DATASET_POOL_SIZE* configuration option.

6.57 GTiff -- GeoTIFF File Format

Driver short name

GTiff

Driver built-in by default

This driver is built-in by default

Most forms of TIFF and GeoTIFF files are supported by GDAL for reading, and somewhat less varieties can be written.

GDAL also supports reading and writing BigTIFF files (evolution of the TIFF format to support files larger than 4 GB).

Currently band types of Byte, UInt16, Int16, UInt32, Int32, Float32, Float64, CInt16, CInt32, CFloat32 and CFloat64 are supported for reading and writing. Paletted images will return palette information associated with the band. The compression formats listed below should be supported for reading as well.

As well, one bit files, and some other unusual formulations of GeoTIFF file, such as YCbCr color model files, are automatically translated into RGBA (red, green, blue, alpha) form, and treated as four eight bit bands.

For an alternative which offers thread-safe read-only capabilities, consult *LIBERTIFF -- GeoTIFF File Format*.

6.57.1 Driver capabilities

Supports CreateCopy()

This driver supports the `GDALDriver::CreateCopy()` operation

Supports Create()

This driver supports the `GDALDriver::Create()` operation

Supports Georeferencing

This driver supports georeferencing

Supports VirtualIO

This driver supports *virtual I/O operations (/vsimem/, etc.)*

6.57.2 Georeferencing

Most GeoTIFF projections should be supported, with the caveat that in order to translate uncommon Projected, and Geographic coordinate systems into OGC WKT it is necessary to have the PROJ proj.db database available. It must be found at the location pointed to by the PROJ_LIB environment variable, or at one of the locations set programmatically via OSRSetPROJSearchPaths().

Georeferencing from GeoTIFF is supported in the form of one tiepoint and pixel size, a transformation matrix, or a list of GCPs.

If no georeferencing information is available in the TIFF file itself, GDAL will also check for, and use an ESRI *world file* with the extension .tfw, .tifw/.tiffw or .wld, as well as a MapInfo .tab file.

By default, information is fetched in following order (first listed is the highest priority): PAM (Persistent Auxiliary metadata) .aux.xml sidecar file, INTERNAL (GeoTIFF keys and tags), TABFILE (.tab), WORLDFILE (.tfw, .tifw/.tiffw or .wld), XML (.xml)

The allowed sources and their priority order can be changed with the `GDAL_GEOREF_SOURCES` configuration option (or `GEOREF_SOURCES` open option) whose value is a comma-separated list of the following keywords : PAM, INTERNAL, TABFILE, WORLDFILE, XML (added in 3.7), NONE. Earlier mentioned sources take priority over later ones. A non mentioned source will be ignored.

For example setting it to "WORLDFILE,PAM,INTERNAL" will make a geotransformation matrix from a potential worldfile priority over PAM or GeoTIFF.

Minimum support for extracting the CRS from ESRI .xml side car files has been added in GDAL 3.7, using the metadata.refSysInfo.RefSystem.refSysID.identCode.code CRS code.

GDAL can read and write the *RPCCoefficientTag* as described in the RPCs in GeoTIFF proposed extension. The tag is written only for files created with the default profile GDALGeoTIFF. For other profiles, a .RPB file is created. In GDAL data model, the RPC coefficients are stored into the RPC metadata domain. For more details, see the rfc-22. If .RPB or _RPC.TXT files are found, they will be used to read the RPCs, even if the *RPCCoefficientTag* tag is set.

6.57.3 Internal nodata masks

TIFF files can contain internal transparency masks. The GeoTIFF driver recognizes an internal directory as being a transparency mask when the FILETYPE_MASK bit value is set on the TIFFTAG_SUBFILETYPE tag. According to the TIFF specification, such internal transparency masks contain 1 sample of 1-bit data. Although the TIFF specification allows for higher resolutions for the internal transparency mask, the GeoTIFF driver only supports internal transparency masks of the same dimensions as the main image. Transparency masks of internal overviews are also supported.

When the `GDAL_TIFF_INTERNAL_MASK` configuration option is set to YES (which is the case starting with GDAL 3.9 when CreateMaskBand() is invoked on the dataset, or when it is invoked on a raster band with the GMF_PER_DATASET flag), and the GeoTIFF file is opened in update mode, the CreateMaskBand() method on a TIFF dataset or rasterband will create an internal transparency mask. Otherwise, the default behavior of nodata mask creation will be used, that is to say the creation of a .msk file, as per rfc-15.

1-bit internal mask band are deflate compressed. When reading them back, to make conversion between mask band and alpha band easier, mask bands are exposed to the user as being promoted to full 8 bits (i.e. the value for unmasked pixels is 255) unless the `GDAL_TIFF_INTERNAL_MASK_TO_8BIT` configuration option is set to NO. This does not affect the way the mask band is written (it is always 1-bit).

6.57.4 Overviews

The GeoTIFF driver supports reading, creation and update of internal overviews. Internal overviews can be created on GeoTIFF files opened in update mode (with gdaladdo for instance). If the GeoTIFF file is opened as read only, the creation of overviews will be done in an external .ovr file. Overview are only updated on request with the BuildOverviews() method.

Several overview creation options are available. They can be provided through `GDALDataset::BuildOverviews()`, `GDALDataset::AddOverviews()` or with the `--creation-option` argument of *gdal raster overview add*.

Most of them can also be specified as configuration options by adding an `_OVERVIEW` suffix to the option name, but this is now considered a legacy behavior.

- **LOCATION=[INTERNAL/EXTERNAL/RRD]:** Set the location of the overview.
  - LOCATION=INTERNAL: only when the dataset to update is a (Geo)TIFF file.
  - LOCATION=EXTERNAL: implied when using option `--external` of *gdal raster overview add*
  - LOCATION=RRD: place the overviews in an associated .aux file suitable for direct use with Imagine or ArcGIS, as well as GDAL applications. Note that none of the below options apply when RRD is selected.
- **COMPRESS=[JPEG/LZW/PACKBITS/DEFLATE/CCITTRLE/CCITTFAX3/CCITTFAX4/LZMA/ZSTD/LERC/LERC_DEFLATE/LERC_ZSTD/WEBP/JXL/NONE]:** Set the compression to use. By default, `NONE`, unless the dataset to update is a (Geo)TIFF file, in which case the compression method of its full resolution layer will be used.
  - `JPEG` should generally only be used with Byte data (8 bit per channel). Better compression for RGB images can be obtained by using the PHOTOMETRIC=YCBCR colorspace with a 4:2:2 subsampling of the Y,Cb,Cr components.

  - CCITTFAX3, CCITTFAX4 or CCITRLE compression should only be used with 1bit (NBITS=1) data
  - LZW, DEFLATE and ZSTD compressions can be used with the PREDICTOR creation option.
  - ZSTD: available for GDAL builds (or libtiff when using external libtiff) against libzstd.
  - LERC and LERC_DEFLATE available for GDAL builds (or libtiff when using external liblerc) against liblerc.
  - LERC_ZSTD is available when LERC and ZSTD are available.
  - JXL is for JPEG-XL, and is only available when using internal libtiff and building GDAL against https://github.com/libjxl/libjxl . Supported data types are Byte, UInt16 and Float32 only.
- **BLOCKSIZE=<integer>:** Sets tile width and height. Must be divisible by 16 and a power-of-two value between 64 and 4096. By default, the block size of the full resolution layer (if tiled) is used, otherwise it defaults to 128. This can also be set with the GDAL_TIFF_OVR_BLOCKSIZE configuration option.
- **NUM_THREADS=[<integer>/ALL_CPUS]:** Defaults to 1. Enable multi-threaded compression by specifying the number of worker threads. Worthwhile for slow compression algorithms such as DEFLATE or LZMA. Will be ignored for JPEG. Default is compression in the main thread.
- **PREDICTOR=[1/2/3]:** Defaults to 1. Set the predictor for LZW, DEFLATE and ZSTD compression. The default is 1 (no predictor), 2 is horizontal differencing and 3 is floating point prediction. PREDICTOR=2 is only supported for 8, 16, 32 and 64 bit samples. PREDICTOR=3 is only supported for 16, 32 and 64 bit floating-point data.
- **JPEG_QUALITY=1-100:** Defaults to 75. Set the JPEG quality when using JPEG compression. Low values result in higher compression ratios, but poorer image quality with strong blocking artifacts. Values above 95 are not meaningfully better quality but can be substantially larger.
- **JPEGTABLESMODE=[0/1/2/3]:** Defaults to 1. Configure how and where JPEG quantization and Huffman tables are written in the TIFF JpegTables tag and strip/tile.
  - 0: JpegTables is not written. Each strip/tile contains its own quantization tables and use optimized Huffman coding.
  - 1: JpegTables is written with only the quantization tables. Each strip/tile refers to those quantized tables and use optimized Huffman coding. This is generally the optimal choice for smallest file size, and consequently is the default.
  - 2: JpegTables is written with only the default Huffman tables. Each strip/tile refers to those Huffman tables (thus no optimized Huffman coding) and contains its own quantization tables (identical). This option has no anticipated practical value.
  - 3: JpegTables is written with the quantization and default Huffman tables. Each strip/tile refers to those tables (thus no optimized Huffman coding). This option could perhaps with some data be more efficient than 1, but this should only occur in rare circumstances.
- **INTERLEAVE=[BAND/PIXEL]:** Control whether pixel or band interleaving is used.
- **PHOTOMETRIC=[MINISBLACK/MINISWHITE/RGB/CMYK/YCBCR/CIELAB/ICCLAB/ITULAB]:** Set the photometric interpretation tag. Default is MINISBLACK, but if the input image has 3 or 4 bands of Byte type, then RGB will be selected. You can override default photometric using this option.
- **ALPHA=[YES/NON-PREMULTIPLIED/PREMULTIPLIED/UNSPECIFIED]:** The first "extrasample" is marked as being alpha if there are any extra samples. This is necessary if you want to produce a greyscale TIFF file with an alpha band (for instance). YES is an alias for NON-PREMULTIPLIED alpha.
- **ZLEVEL=Integer between 1 and 9 (or 12 when libdeflate is used):** (GDAL >= 3.4.1) Defaults to 6. Deflate compression level, for COMPRESS=DEFLATE or LERC_DEFLATE.
- **ZSTD_LEVEL=Integer between 1 and 22:** (GDAL >= 3.4.1) Defaults to 9. ZSTD compression level, for COMPRESS=ZSTD or LERC_ZSTD.

- **WEBP_LEVEL=Integer between 0 and 100:** Defaults to `75`. WEBP quality level of overviews, either internal or external.
- **WEBP_LOSSLESS=[YES/NO]:** (GDAL >= 3.6) Defaults to `NO`. Whether WEBP compression is lossless or not.
- **MAX_Z_ERROR=value:** (GDAL >= 3.4.1) Defaults to `0` (lossless). Maximum error threshold on values for LERC/LERC_DEFLATE/LERC_ZSTD compression.
- **JXL_LOSSLESS=[YES/NO]:** Defaults to `YES`. Set whether JPEG-XL compression should be lossless (YES) or lossy (NO). For lossy compression, the underlying data should be either gray, gray+alpha, rgb or rgb+alpha. For lossy compression, the pixel data should span the whole range of the underlying pixel type (i.e. 0-255 for Byte, 0-65535 for UInt16)
- **JXL_EFFORT=[1-9]:** Defaults to `5`. Level of effort for JPEG-XL compression. The higher, the smaller file and slower compression time.
- **JXL_DISTANCE=[0.01-25]:** Defaults to `1.0`. (Only applies when JXL_LOSSLESS=NO) Distance level for lossy JPEG-XL compression. It is specified in multiples of a just-noticeable difference. (cf butteraugli for the definition of the distance) That is, 0 is mathematically lossless, 1 should be visually lossless, and higher distances yield denser and denser files with lower and lower fidelity. The recommended range is [0.5,3].
- **JXL_ALPHA_DISTANCE=[-1/0/[0.01-25]]:** Defaults to `-1`. (Only applies when JXL_LOSSLESS=NO) Requires libjxl > 0.8.1. Distance level for alpha channel for lossy JPEG-XL compression. It is specified in multiples of a just-noticeable difference. (cf butteraugli for the definition of the distance) That is, 0 is mathematically lossless, 1 should be visually lossless, and higher distances yield denser and denser files with lower and lower fidelity. For lossy compression, the recommended range is [0.5,3]. The default value is the special value -1.0, which means to use the same distance value as non-alpha channel (ie JXL_DISTANCE).
- **SPARSE_OK=[ON/OFF]:** Defaults to `OFF`. When set to ON, blocks whose pixels are all at nodata (or 0 if no nodata is defined) are not written in the file. Sparse files have 0 tile/strip offsets for blocks never written and save space; however, most non-GDAL packages cannot read such files.

6.57.5 Overviews and nodata masks

The following configurations can be encountered depending if overviews and nodata masks are internal or not.

- Internal overviews, internal nodata mask: If a GeoTIFF file has a internal transparency mask and the GeoTIFF file is opened in update mode, BuildOverviews() will automatically create overviews for the internal transparency mask.
- External overviews, external nodata mask: When opened in read-only mode, BuildOverviews() will automatically create overviews for the external transparency mask (in a .msk.ovr file)
- Internal overviews, external nodata mask: when running BuildOverviews() in update mode on the .tif file, starting with GDAL 3.9, overviews of the main bands and of the external .msk will be generated (as internal overview of the .msk). Prior to GDAL 3.9, only the overviews of the main bands are generated. Overviews of the external .msk file had to be explicitly generated by running BuildOverviews() on the .msk.

For the remaining configuration, behavior is less obvious:

- External overviews, internal nodata mask: when running BuildOverviews() in read-only mode on the .tif file, only the overviews of the main bands will be generated. Generating the overviews of the internal nodata mask is not currently supported by the driver.

Practical note: for a command line point of view, BuildOverviews() in update mode means "gdaladdo the.tiff" (without -ro). Whereas BuildOverviews() in read-only mode means "gdaladdo -ro the.tiff".

6.57.6 Metadata

GDAL can deal with the following baseline TIFF tags as dataset-level metadata :

- TIFFTAG_DOCUMENTNAME
- TIFFTAG_IMAGEDESCRIPTION
- TIFFTAG_SOFTWARE
- TIFFTAG_DATETIME
- TIFFTAG_ARTIST
- TIFFTAG_HOSTCOMPUTER
- TIFFTAG_COPYRIGHT
- TIFFTAG_XRESOLUTION
- TIFFTAG_YRESOLUTION
- TIFFTAG_RESOLUTIONUNIT
- TIFFTAG_MINSAMPLEVALUE (read only)
- TIFFTAG_MAXSAMPLEVALUE (read only)
- GEO_METADATA: This tag may be used for embedding XML-encoded instance documents prepared using 19139-based schema (GeoTIFF DGIWG)
- TIFF_RSID: This tag specifies a File Universal Unique Identifier, or RSID, according to DMF definition (GeoTIFF DGIWG)

The name of the metadata item to use is one of the above names ("TIFFTAG_DOCUMENTNAME", ...). On creation, those tags can for example be set with

```
gdal_translate in.tif out.tif -mo {TAGNAME}=VALUE
```

Other non standard metadata items can be stored in a TIFF file created with the profile GDALGeoTIFF (the default, see below in the Creation issues section). Those metadata items are grouped together into a XML string stored in the non standard TIFFTAG_GDAL_METADATA ASCII tag (code 42112). When BASELINE or GeoTIFF profile are used, those non standard metadata items are stored into a PAM .aux.xml file.

The value of GDALMD_AREA_OR_POINT ("AREA_OR_POINT") metadata item is stored in the GeoTIFF key RasterPixelIsPoint for GDALGeoTIFF or GeoTIFF profiles.

XMP metadata can be extracted from the file, and will be reported as XML raw content in the xml:XMP metadata domain.

EXIF metadata can be extracted from the file, and will be reported in the EXIF metadata domain.

6.57.7 Color Profile Metadata

GDAL can deal with the following color profile metadata in the COLOR_PROFILE domain:

- SOURCE_ICC_PROFILE (Base64 encoded ICC profile embedded in file. If available, other tags are ignored.)
- SOURCE_PRIMARIES_RED (xyY in "x,y,1" format for red primary.)
- SOURCE_PRIMARIES_GREEN (xyY in "x,y,1" format for green primary)
- SOURCE_PRIMARIES_BLUE (xyY in "x,y,1" format for blue primary)
- SOURCE_WHITEPOINT (xyY in "x,y,1" format for whitepoint)
- TIFFTAG_TRANSFERFUNCTION_RED (Red table of TIFFTAG_TRANSFERFUNCTION)

- TIFFTAG_TRANSFERFUNCTION_GREEN (Green table of TIFFTAG_TRANSFERFUNCTION)
- TIFFTAG_TRANSFERFUNCTION_BLUE (Blue table of TIFFTAG_TRANSFERFUNCTION)
- TIFFTAG_TRANSFERRANGE_BLACK (Min range of TIFFTAG_TRANSFERRANGE)
- TIFFTAG_TRANSFERRANGE_WHITE (Max range of TIFFTAG_TRANSFERRANGE)

Note that these metadata properties can only be used on the original raw pixel data. If automatic conversion to RGB has been done, the color profile information cannot be used.

All these metadata tags can be overridden and/or used as creation options.

6.57.8 json:ISIS3 Metadata

Added in version 3.13.

It is possible to use `GDALDataset::GetMetadataItem()` to request one particular key in the `json:ISIS3` metadata domain among all the top-level keys that would be returned by `GDALDataset::GetMetadata("json:ISIS3")`.

6.57.9 Nodata value

GDAL stores band nodata value in the non standard TIFFTAG_GDAL_NODATA ASCII tag (code 42113) for files created with the default profile GDALGeoTIFF. Note that all bands must use the same nodata value. When BASELINE or GeoTIFF profile are used, the nodata value is stored into a PAM .aux.xml file.

6.57.10 Raster Attribute Table

Starting with GDAL 3.11, raster attribute tables stored in auxiliary .tif.vat.dbf files, as written by ArcGIS, can be read as GDAL Raster Attribute Table.

Starting with GDAL 3.12, raster attribute tables can be written into and read from the `GDAL_METADATA` TIFF tag. If the *GTIFF_WRITE_RAT_TO_PAM* configuration option is set, raster attribute tables will be written instead into the `.aux.xml` side car file.

6.57.11 Sparse files

GDAL makes a special interpretation of a TIFF tile or strip whose offset and byte count are set to 0, that is to say a tile or strip that has no corresponding allocated physical storage. On reading, such tiles or strips are considered to be implicitly set to 0 or to the nodata value when it is defined. On writing, it is possible to enable generating such files through the Create() interface by setting the *SPARSE_OK* creation option to YES. Then, blocks that are never written through the IWriteBlock()/IRasterIO() interfaces will have their offset and byte count set to 0. This is particularly useful to save disk space and time when the file must be initialized empty before being passed to a further processing stage that will fill it. To avoid ambiguities with another sparse mechanism discussed in the next paragraphs, we will call such files with implicit tiles/strips "TIFF sparse files". They will be likely **not** interoperable with TIFF readers that are not GDAL based and would consider such files with implicit tiles/strips as defective.

This mechanism is extended to the CreateCopy() and Open() interfaces (for update mode) as well. If the *SPARSE_OK* creation option (or the *SPARSE_OK* open option for Open()) is set to YES, even an attempt to write a all 0/nodata block will be detected so that the tile/strip is not allocated (if it was already allocated, then its content will be replaced by the 0/nodata content).

In the case where *SPARSE_OK* is **not** defined (or set to its default value FALSE), for uncompressed files whose nodata value is not set, or set to 0, in Create() and CreateCopy() mode, the driver will delay the allocation of 0-blocks until file closing, so as to be able to write them at the very end of the file, and in a way compatible with the filesystem sparse file mechanisms (to be distinguished from the TIFF sparse file extension discussed earlier). That is that all the empty blocks will be seen as properly allocated from the TIFF point of view (corresponding strips/tiles will have valid offsets and byte counts), but will have no corresponding physical storage. Provided that the filesystem supports such sparse

files, which is the case for most Linux popular filesystems (ext2/3/4, xfs, btfs, ...) or NTFS on Windows. If the file system does not support sparse files, physical storage will be allocated and filled with zeros.

6.57.12 Raw mode

For some TIFF formulations that have "odd" photometric color spaces, on-the-fly decoding as RGBA is done. This might not be desirable in some use cases. This behavior can be disabled by prefixing the filename with GTIFF_RAW:

For example to translate a CMYK file to another one :

```
gdal_translate GTIFF_RAW:in.tif out.tif -co PHOTOMETRIC=CMYK
```

6.57.13 Open options

Open options can be specified in command-line tools using the syntax `-oo <NAME>=<VALUE>` or by providing the appropriate arguments to *GDALOpenEx()* (C) or *gdal.OpenEx* (Python). This driver supports the following open options:

NUM_THREADS=[<number_of_threads>/ALL_CPUS]: Enable multi-threaded compression by specifying the number of worker threads. Worth it for slow compression algorithms such as DEFLATE or LZMA. Default is compression in the main thread. Starting with GDAL 3.6, this option also enables multi-threaded decoding when RasterIO() requests intersect several tiles/strips. The *GDAL_NUM_THREADS* configuration option can also be used as an alternative to setting the open option.

GEOREF_SOURCES=comma-separated list with one or several of PAM, INTERNAL, TABFILE, WORLDFILE or XML (XML added in 3.7): Define which georeferencing sources are allowed and their priority order. See *Georeferencing* paragraph.

SPARSE_OK=[TRUE/FALSE]: Defaults to `FALSE`. Should empty blocks be omitted on disk? When this option is set, any attempt of writing a block whose all pixels are 0 or the nodata value will cause it not to be written at all (unless there is a corresponding block already allocated in the file). Sparse files have 0 tile/strip offsets for blocks never written and save space; however, most non-GDAL packages cannot read such files.

IGNORE_COG_LAYOUT_BREAK=[YES/NO]: (GDAL >= 3.8) Defaults to `NO`. Updating a COG (Cloud Optimized GeoTIFF) file generally breaks part of the optimizations, but still produces a valid GeoTIFF file. Starting with GDAL 3.8, to avoid undesired loss of the COG characteristics, opening such a file in update mode will be rejected, unless this option is also set to YES (default is NO). This option has only effect on COG files and when opening in update mode, and is ignored on regular (Geo)TIFF files.

COLOR_TABLE_MULTIPLIER=[AUTO/1/256/257]: (GDAL >= 3.10.0) Specifies the value by which to multiply GDAL color table entry values, usually in [0,255] range, to obtain a TIFF color map value, or on reading by which to divide TIFF color map values to get a GDAL color table entry. GDAL consistently uses 257, but it might be necessary to use 256 for compatibility with files generated by other software. In AUTO mode, GDAL 3.10 or later can automatically detect the 256 multiplication factor when all values in the TIFF color map are multiple of that value.

6.57.14 Creation Issues

GeoTIFF files can be created with any GDAL defined band type, including the complex types. Created files may have any number of bands. Files of type Byte with exactly 3 bands will be given a photometric interpretation of RGB, files of type Byte with exactly four bands will have a photometric interpretation of RGBA, while all other combinations will have a photometric interpretation of MIN_IS_BLACK. Non-standard (regarding to the intrinsics TIFF capabilities) band color interpretation, such as BGR ordering, will be handled in creation and reading, by storing them in the GDAL internal metadata TIFF tag.

The TIFF format only supports R,G,B components for palettes / color tables. Thus on writing the alpha information will be silently discarded.

6.57.14.1 Creation Options

Creation options can be specified in command-line tools using the syntax `-co <NAME>=<VALUE>` or by providing the appropriate arguments to *`GDALCreate()`* (C) or *`Driver.Create`* (Python). This driver supports the following creation options:

- **TFW=[YES/NO]:** Force the generation of an associated ESRI world file (.tfw). See the *World Files* page for details.
- **RPB=[YES/NO]:** Force the generation of an associated .RPB file to describe RPC (Rational Polynomial Coefficients), if RPC information is available. If not specified, this file is automatically generated if there's RPC information and that the PROFILE is not the default GDALGeoTIFF.
- **RPCTXT=[YES/NO]:** Force the generation of an associated _RPC.TXT file to describe RPC (Rational Polynomial Coefficients), if RPC information is available.
- **INTERLEAVE=[BAND/PIXEL]:** Set the interleaving to use. See *Multiband pixel organization (INTERLEAVE metadata item)* for more details.
  - `PIXEL`: for each spatial block, one TIFF tile/strip gathering values for all bands is used . This matches the `contiguous` planar configuration in TIFF terminology. This is also known as a `BIP (Band Interleaved Per Pixel)` organization. Such method is the default, and may be slightly less efficient than BAND interleaving for some purposes, but some applications only support pixel interleaved TIFF files. On the other hand, image-based compression methods may perform better using PIXEL interleaving. For JPEG PHOTOMETRIC=YCbCr, pixel interleaving is required. It is also required for WebP compression.

    Assuming a pixel[band][y][x] indexed array, when using CreateCopy(), the pseudo code for the file disposition is:

    ```
    for y in 0 ... numberOfBlocksInHeight - 1:
        for x in 0 ... numberOfTilesInWidth - 1:
            for j in 0 ... blockHeight - 1:
                for i in 0 ... blockWidth -1:
                    start_new_strip_or_tile()
                    for band in 0 ... numberBands -1:
                        write(pixel[band][y*blockHeight+j][x*blockWidth+i])
                    end_new_strip_or_tile()
                end_for
            end_for
        end_for
    end_for
    ```

  - `BAND`: for each spatial block, one TIFF tile/strip is used for each band. This matches the contiguous `separate` configuration in TIFF terminology. This is also known as a `BSQ (Band SeQuential)` organization.

    In addition to that, when using CreateCopy(), data for the first band is written first, followed by data for the second band, etc. The pseudo code for the file disposition is:

    ```
    for y in 0 ... numberOfBlocksInHeight - 1:
        for x in 0 ... numberOfTilesInWidth - 1:
            start_new_strip_or_tile()
            for band in 0 ... numberBands -1:
                for j in 0 ... blockHeight - 1:
                    for i in 0 ... blockWidth -1:
                        write(pixel[band][y*blockHeight+j][x*blockWidth+i])
                    end_for
                end_for
    ```

(continues on next page)

(continued from previous page)

```
        end_new_strip_or_tile()
    end_for
end_for
```

Starting with GDAL 3.5, when copying from a source dataset with multiple bands which advertises a INTERLEAVE metadata item, if the INTERLEAVE creation option is not specified, the source dataset INTERLEAVE will be automatically taken into account, unless the COMPRESS creation option is specified.

> **Note**
>
> Starting with GDAL 3.11, a `TILE` interleaving is available, but only when using the *COG -- Cloud Optimized GeoTIFF generator* driver.

- **TILED=[YES/NO]:** Defaults to `NO`. By default striped TIFF files are created. This option can be used to force creation of tiled TIFF files.
- **BLOCKXSIZE=<integer>:** Defaults to `256`. Sets tile width. Must be divisible by 16.
- **BLOCKYSIZE=<integer>:** Set tile or strip height. Tile height defaults to 256, strip height defaults to a value such that one strip is 8K or less. Must be divisible by 16 when *TILED*=YES.
- **NBITS=<value>:** Create a file with less than 8 bits per sample by passing a value from 1 to 7. The apparent pixel type should be Byte. Values of n=9...15 (UInt16 type) and n=17...31 (UInt32 type) are also accepted. n=16 is accepted for Float32 type to generate half-precision floating point values.
- **COMPRESS=[JPEG/LZW/PACKBITS/DEFLATE/CCITTRLE/CCITTFAX3/CCITTFAX4/LZMA/ZSTD/LERC/LERC_DEFLATE/LERC_ZSTD/WEBP/JXL/NONE]:** Set the compression to use.
  - `JPEG` should generally only be used with Byte data (8 bit per channel). Better compression for RGB images can be obtained by using the PHOTOMETRIC=YCBCR colorspace with a 4:2:2 subsampling of the Y,Cb,Cr components.

    Starting with GDAL 3.4, if GDAL is built with its internal libtiff, read and write support for JPEG-in-TIFF compressed images with 12-bit sample is enabled by default (if JPEG support is also enabled), using GDAL internal libjpeg (based on IJG libjpeg-6b, with additional changes for 12-bit sample support). Support for JPEG with 12-bit sample is independent of whether 8-bit JPEG support is enabled through internal IJG libjpeg-6b or external libjpeg (like libjpeg-turbo)
  - `CCITTFAX3`, `CCITTFAX4` or `CCITRLE` compression should only be used with 1bit (NBITS=1) data
  - `LZW`, `DEFLATE` and `ZSTD` compressions can be used with the PREDICTOR creation option.
  - `ZSTD` is available when using internal libtiff and if GDAL built against libzstd >=1.0, or if built against external libtiff with zstd support.
  - `LERC` and `LERC_DEFLATE` are available only when using internal libtiff for GDAL < 3.3.0. Since GDAL 3.3.0, LERC compression is also available when building GDAL against external libtiff >= 4.3.0, built itself against https://github.com/esri/lerc
  - `LERC_ZSTD` is available when `LERC` and `ZSTD` are available.
  - `JXL` is for JPEG-XL, and is only available when using internal libtiff and building GDAL against https://github.com/libjxl/libjxl . It is recommended to use JXL compression with the `TILED=YES` creation option and block size of 256x256, 512x512, or 1024x1024 pixels. Supported data types are `Byte`, `UInt16` and `Float32` only. For GDAL < 3.6.0, JXL compression may only be used alongside `INTERLEAVE=PIXEL` (the default) on datasets with 4 bands or less.
  - `NONE` is the default.

- **NUM_THREADS=[<integer>/ALL_CPUS]:** Defaults to 1. Enable multi-threaded compression by specifying the number of worker threads. Worthwhile for slow compression algorithms such as DEFLATE or LZMA. Will be ignored for JPEG. Default is compression in the main thread.
- **PREDICTOR=[1/2/3]:** Defaults to 1. Set the predictor for LZW, DEFLATE and ZSTD compression. The default is 1 (no predictor), 2 is horizontal differencing and 3 is floating point prediction. PREDICTOR=2 is only supported for 8, 16, 32 and 64 bit samples (support for 64 bit was added in libtiff > 4.3.0). PREDICTOR=3 is only supported for 16, 32 and 64 bit floating-point data.
- **DISCARD_LSB=[<nbits>/nbits_band1,nbits_band2,...nbits_bandN]:** Set the number of least-significant bits to clear, possibly different per band. Lossy compression scheme to be best used with PREDICTOR=2 and LZW/DEFLATE/ZSTD compression.
- **SPARSE_OK=[TRUE/FALSE]:** Should newly created files (through Create() interface) be allowed to be sparse? Sparse files have 0 tile/strip offsets for blocks never written and save space; however, most non-GDAL packages cannot read such files. SPARSE_OK=TRUE is also supported through the CreateCopy() interface. Even an attempt to write a block whose all pixels are 0 or the nodata value will cause it not to be written at all (unless there is a corresponding block already allocated in the file). The default is FALSE.
- **JPEG_QUALITY=1-100:** Defaults to 75. Set the JPEG quality when using JPEG compression. Low values result in higher compression ratios, but poorer image quality with strong blocking artifacts. Values above 95 are not meaningfully better quality but can be substantially larger.
- **JPEGTABLESMODE=[0/1/2/3]:** Defaults to 1. Configure how and where JPEG quantization and Huffman tables are written in the TIFF JpegTables tag and strip/tile.
  - 0: JpegTables is not written. Each strip/tile contains its own quantization tables and use optimized Huffman coding.
  - 1: JpegTables is written with only the quantization tables. Each strip/tile refers to those quantized tables and use optimized Huffman coding. This is generally the optimal choice for smallest file size, and consequently is the default.
  - 2: JpegTables is written with only the default Huffman tables. Each strip/tile refers to those Huffman tables (thus no optimized Huffman coding) and contains its own quantization tables (identical). This option has no anticipated practical value.
  - 3: JpegTables is written with the quantization and default Huffman tables. Each strip/tile refers to those tables (thus no optimized Huffman coding). This option could perhaps with some data be more efficient than 1, but this should only occur in rare circumstances.
- **ZLEVEL=[1-9] or [1-12]:** Defaults to 6. Set the level of compression when using DEFLATE compression (or LERC_DEFLATE). A value of 9 (resp. 12) is best/slowest when using zlib (resp. libdeflate), and 1 is least/fastest compression.
- **ZSTD_LEVEL=[1-22]:** Defaults to 9. Set the level of compression when using ZSTD compression (or LERC_ZSTD). A value of 22 is best (very slow), and 1 is least compression.
- **MAX_Z_ERROR=<threshold>:** Defaults to 0. Set the maximum error threshold on values for LERC/LERC_DEFLATE/LERC_ZSTD compression. The default is 0 (lossless).
- **MAX_Z_ERROR_OVERVIEW=<threshold>:** (GDAL >= 3.8) Set the maximum error threshold on values for LERC/LERC_DEFLATE/LERC_ZSTD compression, on overviews. The default is the value of *MAX_Z_ERROR*
- **WEBP_LEVEL=[1-100]:** Defaults to 75. Set the WEBP quality level when using WEBP compression. A value of 100 is best quality (least compression), and 1 is worst quality (best compression).
- **WEBP_LOSSLESS=[TRUE/FALSE]:** Requires libwebp >= 0.1.4. By default, lossy compression is used. If set to True, lossless compression will be used. There is a significant time penalty for each tile/strip with lossless WebP compression, so you may want to increase the *BLOCKYSIZE* value for strip layout.

- **JXL_LOSSLESS=[YES/NO]:** Defaults to `YES`. Set whether JPEG-XL compression should be lossless (YES) or lossy (NO). For lossy compression, the underlying data should be either gray, gray+alpha, rgb or rgb+alpha. For lossy compression, the pixel data should span the whole range of the underlying pixel type (i.e. 0-255 for Byte, 0-65535 for UInt16)
- **JXL_EFFORT=[1-9]:** Defaults to `5`. Level of effort for JPEG-XL compression. The higher, the smaller file and slower compression time.
- **JXL_DISTANCE=[0.01-25]:** Defaults to `1.0`. (Only applies when JXL_LOSSLESS=NO) Distance level for lossy JPEG-XL compression. It is specified in multiples of a just-noticeable difference. (cf butteraugli for the definition of the distance) That is, 0 is mathematically lossless, 1 should be visually lossless, and higher distances yield denser and denser files with lower and lower fidelity. The recommended range is [0.5,3].
- **JXL_ALPHA_DISTANCE=[-1/0/[0.01-25]]:** (GDAL >= 3.7) Defaults to `-1`. (Only applies when JXL_LOSSLESS=NO) Requires libjxl > 0.8.1. Distance level for alpha channel for lossy JPEG-XL compression. It is specified in multiples of a just-noticeable difference. (cf butteraugli for the definition of the distance) That is, 0 is mathematically lossless, 1 should be visually lossless, and higher distances yield denser and denser files with lower and lower fidelity. For lossy compression, the recommended range is [0.5,3]. The default value is the special value -1.0, which means to use the same distance value as non-alpha channel (ie JXL_DISTANCE).
- **PHOTOMETRIC=[MINISBLACK/MINISWHITE/RGB/CMYK/YCBCR/CIELAB/ICCLAB/ITULAB]:** Set the photometric interpretation tag. Default is MINISBLACK, but if the input image has 3 or 4 bands of Byte type, then RGB will be selected. You can override default photometric using this option.
- **ALPHA=[YES/NON-PREMULTIPLIED/PREMULTIPLIED/UNSPECIFIED]:** The first "extrasample" is marked as being alpha if there are any extra samples. This is necessary if you want to produce a greyscale TIFF file with an alpha band (for instance). YES is an alias for NON-PREMULTIPLIED alpha.
- **PROFILE=[GDALGeoTIFF/GeoTIFF/BASELINE]:** Defaults to `GDALGeoTIFF`. Control what non-baseline tags are emitted by GDAL.
  - With `GDALGeoTIFF` (the default) various GDAL custom tags may be written.
  - With `GeoTIFF` only GeoTIFF tags will be added to the baseline.
  - With `BASELINE` no GDAL or GeoTIFF tags will be written. BASELINE is occasionally useful when writing files to be read by applications intolerant of unrecognized tags.
- **BIGTIFF=[YES/NO/IF_NEEDED/IF_SAFER]:** Defaults to `IF_NEEDED`. Control whether the created file is a BigTIFF or a classic TIFF.
  - `YES` forces BigTIFF.
  - `NO` forces classic TIFF.
  - `IF_NEEDED` will only create a BigTIFF if it is clearly needed (in the uncompressed case, and image larger than 4GB. So no effect when using a compression).
  - `IF_SAFER` will create BigTIFF if the resulting file *might* exceed 4GB. Note: this is only a heuristic that might not always work depending on compression ratios.

  BigTIFF is a TIFF variant which can contain more than 4GiB of data (size of classic TIFF is limited by that value). This option is available if GDAL is built with libtiff library version 4.0 or higher.

  When creating a new GeoTIFF with no compression, GDAL computes in advance the size of the resulting file. If that computed file size is over 4GiB, GDAL will automatically decide to create a BigTIFF file. However, when compression is used, it is not possible in advance to known the final size of the file, so classical TIFF will be chosen. In that case, the user must explicitly require the creation of a BigTIFF with *`BIGTIFF=YES`* if the final file is anticipated to be too big for classical TIFF format. If BigTIFF creation is not explicitly asked or guessed and the resulting file is too big for classical TIFF, libtiff will fail with an error message like "TIFFAppendToStrip:Maximum TIFF file size exceeded".

- **PIXELTYPE=[DEFAULT/SIGNEDBYTE]:** By setting this to `SIGNEDBYTE`, a new Byte file can be forced to be written as signed byte. Starting with GDAL 3.7, this option is deprecated and Int8 should rather be used.
- **COPY_SRC_OVERVIEWS=[YES/NO]:** Defaults to `NO`. Used by (*`GDALDriver::CreateCopy()`* only) By setting this to YES, the potential existing overviews of the source dataset will be copied to the target dataset without being recomputed. This option is typically used to generate Cloud Optimized Geotiff (starting with GDAL 3.1, the *COG -- Cloud Optimized GeoTIFF generator* driver can be used as a convenient shortcut). If overviews of mask band also exist, provided that the *`GDAL_TIFF_INTERNAL_MASK`* configuration option is set to YES (which is the case starting with GDAL 3.9), they will also be copied. Note that this creation option will have no effect if general options (i.e. options which are not creation options) of gdal_translate are used. Creation options related to compression are also applied to the output overviews.
- **STREAMABLE_OUTPUT=[YES/NO]:** Generate a file with an Image File Directory and block order that allow streaming. See *Streaming operations*.
- **GEOTIFF_KEYS_FLAVOR=[STANDARD/ESRI_PE]:** Defaults to `STANDARD`. Determine which "flavor" of GeoTIFF keys must be used to write the SRS information. The STANDARD way (default choice) will use the general accepted formulations of GeoTIFF keys, including extensions of the values accepted for ProjectedCSTypeGeoKey to new EPSG codes. The ESRI_PE flavor will write formulations that are (more) compatible with ArcGIS. At the time of writing, the ESRI_PE choice has mostly an effect when writing the EPSG:3857 (Web Mercator) SRS. For other SRS, the standard way will be used, with the addition of a ESRI_PE WKT string as the value of PCSCitationGeoKey.
- **GEOTIFF_VERSION=[AUTO/1.0/1.1]:** (GDAL >= 3.1.0) Defaults to `AUTO`. Select the version of the GeoTIFF standard used to encode georeferencing information. `1.0` corresponds to the original 1995, GeoTIFF Revision 1.0, by Ritter & Ruth. `1.1` corresponds to the OGC standard 19-008, which is an evolution of 1.0, which clear ambiguities and fix inconsistencies mostly in the processing of the vertical part of a CRS. `AUTO` mode (default value) will generally select 1.0, unless the CRS to encode has a vertical component or is a 3D CRS, in which case 1.1 is used.

  > **Note**
  >
  > Write support for GeoTIFF 1.1 requires libgeotiff 1.6.0 or later.

- **COLOR_TABLE_MULTIPLIER=[1/256/257]:** (GDAL >= 3.10.0) Defaults to `257`. Specifies the value by which to multiply GDAL color table entry values, usually in [0,255] range, to obtain a TIFF color map value. GDAL consistently uses 257, but it might be necessary to use 256 for compatibility with files generated by other software.

6.57.14.2 Subdatasets

Multi-page TIFF files are exposed as subdatasets. On opening, a subdataset name is GTIFF_DIR:{index}:filename.tif, where {index} starts at 1.

Starting with GDAL 3.0, subdataset creation is possible by using the APPEND_SUBDATASET=YES creation option. The filename passed to Create() / CreateCopy() should be the regular filename (not with GTIFF_DIR: syntax. Creating overviews on a multi-page TIFF is not supported.

Starting with GDAL 3.2, read-only access to subdataset overviews and masks is possible provided that they are referenced by their parent IFD through the TIFFTAG_SUBIFD tag.

6.57.14.3 About JPEG compression of RGB images

When translating a RGB image to JPEG-In-TIFF, using PHOTOMETRIC=YCBCR can make the size of the image typically 2 to 3 times smaller than the default photometric value (RGB). When using PHOTOMETRIC=YCBCR, the INTERLEAVE option must be kept to its default value (PIXEL), otherwise libtiff will fail to compress the data.

Note also that the dimensions of the tiles or strips must be a multiple of 8 for PHOTOMETRIC=RGB or 16 for PHOTOMETRIC=YCBCR

6.57.14.4 Lossless conversion of JPEG into JPEG-in-TIFF

The conversion of a JPEG file (but *not* a JPEG-in-TIFF file) to a JPEG-in-TIFF file without decompression and compression cycles, and thus without any additional quality loss, can be done with gdal_translate (or the CreateCopy() API), if all the following conditions are met:

- the source dataset is a JPEG file (or a VRT with a JPEG as a single SimpleSource)
- the target dataset is a JPEG-in-TIFF file
- no explicitly target JPEG quality is specified
- no change in colorspace is specified
- no sub-windowing is requested
- and more generally, no change that alters pixel values

The generation of a tiled JPEG-in-TIFF from the original JPEG image is possible. Explicit assignment of target SRS and bounds are also possible.

So, the following commands will use the lossless copy method :

```
gdal_translate in.jpg out.tif -co COMPRESS=JPEG

gdal_translate in.jpg out.tif -co COMPRESS=JPEG -co TILED=YES

gdal_translate in.jpg out.tif -co COMPRESS=JPEG -a_srs EPSG:4326 -a_ullr -180 90 180 -90
```

whereas the following commands will *not* (and thus cause JPEG decompression and compression):

```
gdal_translate in.jpg out.tif -co COMPRESS=JPEG -co JPEG_QUALITY=60

gdal_translate in.jpg out.tif -srcwin 0 0 500 500 -co COMPRESS=JPEG
```

6.57.14.5 Streaming operations

The GeoTIFF driver can support reading or writing TIFF files (with some restrictions detailed below) in a streaming compatible way.

When reading a file from /vsistdin/, a named pipe (on Unix), or if forcing streamed reading by setting the *TIFF_READ_STREAMING* configuration option to YES, the GeoTIFF driver will assume that the TIFF Image File Directory (IFD) is at the beginning of the file, i.e. at offset 8 for a classical TIFF file or at offset 16 for a BigTIFF file. The values of the tags of array type must be contained at the beginning of file, after the end of the IFD and before the first image strip/tile. The reader must read the strips/tiles in the order they are written in the file. For a pixel interleaved file (PlanarConfiguration=Contig), the recommended order for a writer, and thus for a reader, is from top to bottom for a strip-organized file or from top to bottom, which a chunk of a block height, and left to right for a tile-organized file. For a band organized file (PlanarConfiguration=Separate), the above order is recommended with the content of the first band, then the content of the second band, etc... Technically this order corresponds to increasing offsets in the TileOffsets/StripOffsets tag. This is the order that the GDAL raster copy routine will assume.

If the order is not the one described above, the UNORDERED_BLOCKS=YES dataset metadata item will be set in the TIFF metadata domain. Each block offset can be determined by querying the "BLOCK_OFFSET_[xblock]_[yblock]" band metadata items in the TIFF metadata domain (where xblock, yblock is the coordinate of the block), and a reader could use that information to determine the appropriate reading order for image blocks.

The files that are streamed into the GeoTIFF driver may be compressed, even if the GeoTIFF driver cannot produce such files in streamable output mode (regular creation of TIFF files will produce such compatible files for streamed reading).

When writing a file to /vsistdout/, a named pipe (on Unix), or when defining the *STREAMABLE_OUTPUT=YES* creation option, the CreateCopy() method of the GeoTIFF driver will generate a file with the above defined constraints (related to position of IFD and block order), and this is only supported for a uncompressed file. The Create() method also supports creating streamable compatible files, but the writer must be careful to set the projection, geotransform or metadata before writing image blocks (so that the IFD is written at the beginning of the file). And when writing image blocks, the order of blocks must be the one of the above paragraph, otherwise errors will be reported.

Some examples :

```
gdal_translate in.tif /vsistdout/ -co TILED=YES | gzip | gunzip | gdal_translate /
↪vsistdin/ out.tif -co TILED=YES -co COMPRESS=DEFLATE
```

or

```
mkfifo my_fifo
gdalwarp in.tif my_fifo -t_srs EPSG:3857
gdal_translate my_fifo out.png -of PNG
```

Note: not all utilities are compatible with such input or output streaming operations, and even those which may deal with such files may not manage to deal with them in all circumstances, for example if the reading driver driven by the output file is not compatible with the block order of the streamed input.

6.57.14.6 Configuration options

Configuration options can be specified in command-line tools using the syntax `--config <NAME>=<VALUE>` or using functions such as *CPLSetConfigOption()* (C) or *gdal.config_options* (Python). This paragraph lists the configuration options that can be set to alter the default behavior of the GTiff driver.

- **GTIFF_IGNORE_READ_ERRORS=[TRUE/FALSE]:** Can be set to TRUE to avoid turning libtiff errors into GDAL errors. Can help reading partially corrupted TIFF files.
- **ESRI_XML_PAM=[TRUE/FALSE]:** Can be set to TRUE to force metadata in the xml:ESRI domain to be written to PAM.
- **BIGTIFF_OVERVIEW=value:** Control whether BigTIFF should be used for overviews. Options are the same as *BIGTIFF* creation option.
- **COMPRESS_OVERVIEW=value:** See *COMPRESS* creation option. Set the compression type to use for overviews. For internal overviews, only honoured since GDAL 3.6.
- **INTERLEAVE_OVERVIEW=[BAND/PIXEL]:** Control whether pixel or band interleaving is used for overviews.
- **PHOTOMETRIC_OVERVIEW=value:** Set the photometric color space for overview creation
- **PREDICTOR_OVERVIEW=[1/2/3]:** Set the predictor to use for overviews with LZW, DEFLATE and ZSTD compression.
- **JPEG_QUALITY_OVERVIEW=Integer between 0 and 100:** Defaults to `75`. Quality of JPEG compressed overviews, either internal or external.

- **WEBP_LEVEL_OVERVIEW=Integer between 0 and 100:** Defaults to `75`. WEBP quality level of overviews, either internal or external.
- **WEBP_LOSSLESS_OVERVIEW=[YES/NO]:** (GDAL >= 3.6) Defaults to `NO`. Whether WEBP compression is lossless or not.
- **ZLEVEL_OVERVIEW=Integer between 1 and 9 (or 12 when libdeflate is used):** (GDAL >= 3.4.1) Defaults to `6`. Deflate compression level of overviews, for COMPRESS_OVERVIEW=DEFLATE or LERC_DEFLATE, either internal or external.
- **ZSTD_LEVEL_OVERVIEW=Integer between 1 and 22:** (GDAL >= 3.4.1) Defaults to `9`. ZSTD compression level of overviews, for COMPRESS_OVERVIEW=ZSTD or LERC_ZSTD, either internal or external.
- **MAX_Z_ERROR_OVERVIEW=value:** (GDAL >= 3.4.1) Defaults to `0` (lossless). Maximum error threshold on values for LERC/LERC_DEFLATE/LERC_ZSTD compression of overviews, either internal or external.
- **SPARSE_OK_OVERVIEW=[ON/OFF]:** (GDAL >= 3.4.1) Defaults to `OFF`. When set to ON, blocks whose pixels are all at nodata (or 0 if no nodata is defined) are not written in the file. Sparse files have 0 tile/strip offsets for blocks never written and save space; however, most non-GDAL packages cannot read such files.
- **GDAL_TIFF_INTERNAL_MASK=[TRUE/FALSE]:** Defaults to `TRUE` (since GDAL 3.9), FALSE (GDAL 3.8 or earlier). See *Internal nodata masks* section
- **GDAL_TIFF_INTERNAL_MASK_TO_8BIT=[TRUE/FALSE]:** Defaults to `TRUE`. See *Internal nodata masks* section.
- *USE_RRD*: Can be set to TRUE to force external overviews in the RRD format.
- **TIFF_USE_OVR=[TRUE/FALSE]:** Defaults to `FALSE`. Can be set to TRUE to force external overviews in the GeoTIFF (.ovr) format.
- **TIFF_READ_STREAMING=[YES/NO]:** If `YES`, assume that Image File Directory is at the beginning of the file. See *Streaming operations*.
- **GTIFF_POINT_GEO_IGNORE=[TRUE/FALSE]:** Defaults to `FALSE`. Can be set to TRUE to revert back to the behavior of ancient GDAL versions regarding how PixelIsPoint is interpreted w.r.t geotransform. See rfc-33 for more details.
- **GTIFF_REPORT_COMPD_CS=[TRUE/FALSE]:** Can be set to TRUE to avoid stripping the vertical CRS of compound CRS when reading the SRS of a file. Does not affect the writing side. Default value : FALSE for GeoTIFF 1.0 files, or TRUE (starting with GDAL 3.1) for GeoTIFF 1.1 files.
- **GDAL_ENABLE_TIFF_SPLIT=[TRUE/FALSE]:** Defaults to `TRUE`. Can be set to FALSE to avoid all-in-one-strip files being presented as having.
- **GDAL_TIFF_OVR_BLOCKSIZE=value:** See *Overviews* section.
- **GTIFF_LINEAR_UNITS=value:** Can be set to BROKEN to read GeoTIFF files that have false easting/northing improperly set in meters when it ought to be in coordinate system linear units. (Ticket #3901).
- **TAB_APPROX_GEOTRANSFORM=[YES/NO]:** Defaults to `NO`. To decide if an approximate geotransform is acceptable when reading a .tab file.
- **GTIFF_DIRECT_IO=[YES/NO]:** Defaults to `NO`. Can be set to YES to use specialized RasterIO() implementations when reading un-compressed TIFF files to avoid using the block cache. Setting it to YES even when the optimized cases do not apply should be safe (generic implementation will be used).
- **GTIFF_VIRTUAL_MEM_IO=[YES/NO/IF_ENOUGH_RAM]:** Defaults to `NO`. Can be set to YES to use specialized RasterIO() implementations when reading un-compressed TIFF files to avoid using the block cache. This implementation relies on memory-mapped file I/O, and is currently only supported on Linux (64-bit build strongly recommended) or, on other POSIX-like systems. Setting it to YES even when the optimized cases do not apply should be safe (generic implementation will be used), but if the file exceeds RAM, disk swapping might occur if the whole file is read. Setting it to IF_ENOUGH_RAM will first check if the uncompressed file size is

no bigger than the physical memory. If both *GTIFF_VIRTUAL_MEM_IO* and *GTIFF_DIRECT_IO* are enabled, the former is used in priority, and if not possible, the later is tried.

- *GDAL_NUM_THREADS* enables multi-threaded compression by specifying the number of worker threads. Worth it for slow compression algorithms such as DEFLATE or LZMA. Will be ignored for JPEG. Default is compression in the main thread. Note: this configuration option also apply to other parts to GDAL (warping, gridding, ...). Starting with GDAL 3.6, this option also enables multi-threaded decoding when RasterIO() requests intersect several tiles/strips.
- **GTIFF_WRITE_RAT_TO_PAM=[YES/NO]:** (GDAL >= 3.12.0) Defaults to `YES`. Whether raster attribute tables attached to bands of a GeoTIFF dataset must be serialized in the `.aux.xml` side-car file, instead of the `GDAL_METADATA` TIFF tag. In versions prior to 3.12, raster attribute tables were always written and read in the `.aux.xml` side-car file.
- **GTIFF_WRITE_TOWGS84=[AUTO/YES/NO]:** (GDAL >= 3.0.3) When set to AUTO, a GeogTOWGS84GeoKey geokey will be written with TOWGS84 3 or 7-parameter Helmert transformation, if the CRS has no EPSG code attached to it, or if the TOWGS84 transformation attached to the CRS doesn't match the one imported from the EPSG code. If set to YES, then the TOWGS84 transformation attached to the CRS will be always written. If set to NO, then the transformation will not be written in any situation.
- **CHECK_DISK_FREE_SPACE=[YES/NO]:** Defaults to `YES`. If `YES`, ensure that enough disk space is available before attempting to write an uncompressed, non-sparse GeoTIFF. Disabling this check is not expected to be necessary, unless GDAL is incorrectly determining the disk space available on the destination file system.
- **GTIFF_READ_ANGULAR_PARAMS_IN_DEGREE=[YES/NO]:** (GDAL >= 3.9.1) Defaults to `NO`. Conformant GeoTIFF files should have the values of angular projection parameters written in the unit of the GeogAngularUnitsGeoKey. But some non-conformant implementations, such as GDAL <= 3.9.0, always wrote them in degrees. This option can be set to YES when reading such non-conformant GeoTIFF files (typically using grads), to instruct GDAL (>= 3.9.1) that the projection parameters are in degrees, instead of being expressed in the unit of the GeogAngularUnitsGeoKey.
- **GTIFF_WRITE_ANGULAR_PARAMS_IN_DEGREE=[YES/NO]:** (GDAL >= 3.9.1) Defaults to `NO`. Conformant GeoTIFF files should have the values of angular projection parameters written in the unit of the GeogAngularUnitsGeoKey. But some non-conformant implementations, such as GDAL >= 3.0 and <= 3.9.0, assumed those values to be in degree. This option can be set to YES to force writing such non-conformant GeoTIFF files. It should *not* be nominally used, except to workaround interoperability issues.

6.57.15 Codec Recommendations

6.57.15.1 LZW

If you don't know what to choose, choose this one.

6.57.15.2 DEFLATE

The most commonly supported TIFF codec, especially with older non-geo software.

6.57.15.3 LERC

Used for storing quantized floating point data. https://github.com/esri/lerc

6.57.15.4 ZSTD

Smaller and faster than DEFLATE, but not as commonly supported.

6.57.15.5 WEBP

A smaller and faster JPEG.

6.57.15.6 JXL

Next-gen JPG from the JPG group.

6.57.15.7 LZMA

Slow but storage efficient.

6.57.15.8 CCITTRLE/CCITTFAX3/CCITTFAX4

Did you happen to have fax files from the 1990s? Use these.

6.57.16 See Also

- GeoTIFF Information Page

- Details on BigTIFF file format
- *COG -- Cloud Optimized GeoTIFF generator* driver

6.57.16.1 WLD -- ESRI World File

A world file file is a plain ASCII text file consisting of six values separated by newlines. The format is:

```
pixel X size
rotation about the Y axis (usually 0.0)
rotation about the X axis (usually 0.0)
negative pixel Y size
X coordinate of upper left pixel center
Y coordinate of upper left pixel center
```

For example:

```
60.0000000000
0.0000000000
0.0000000000
-60.0000000000
440750.0000000000
3751290.0000000000
```

You can construct that file simply by using your favorite text editor.

World file usually has suffix `.wld`, but sometimes it may has `.tfw`, `.tifw`, `.jgw` or other suffixes depending on the image file it comes with.

6.58 GXF -- Grid eXchange File

Driver short name

GXF

Driver built-in by default

This driver is built-in by default

This is a raster exchange format propagated by Geosoft, and made a standard in the gravity/magnetics field. GDAL supports reading (but not writing) GXF-3 files, including support for georeferencing information, and projections.

By default, the datatype returned for GXF datasets by GDAL is Float32. You can specify the datatype by setting the GXF_DATATYPE configuration option (Float64 supported currently)

Details on the supporting code, and format can be found on the GXF-3 page.

NOTE: Implemented as gxfdataset.cpp.

6.58.1 Driver capabilities

Supports Georeferencing

This driver supports georeferencing

Supports VirtualIO

This driver supports *virtual I/O operations (/vsimem/, etc.)*

6.59 GTX — NOAA Vertical Datum Grid Shift

Driver short name

GTX

Driver built-in by default

This driver is built-in by default

The GTX format is used to store vertical datum grid shift grids, typically distributed by NOAA. These grids have been used historically by PROJ, until PROJ 7.0 where GeoTIFF-based grids have been introduced and are now the preferred way to convey geoid models.

6.59.1 Driver capabilities

- Read-only
- Raster

Supports CreateCopy()

This driver supports the `GDALDriver::CreateCopy()` operation

Supports Create()

This driver supports the `GDALDriver::Create()` operation

Supports Georeferencing

This driver supports georeferencing

Supports VirtualIO

This driver supports *virtual I/O operations (/vsimem/, etc.)*

6.59.2 File format

GTX files are binary raster grids containing vertical offset values. They are commonly used in conjunction with coordinate reference systems that include vertical components.

6.59.3 See also

6.60 HDF4 -- Hierarchical Data Format Release 4 (HDF4)

Driver short name

HDF4

Driver short name

HDF4Image

Build dependencies

libdf

There are two HDF formats, HDF4 (4.x and previous releases) and HDF5. These formats are completely different and NOT compatible. This driver intended for HDF4 file formats importing. NASA's Earth Observing System (EOS) maintains its own HDF modification called HDF-EOS. This modification is suited for use with remote sensing data and fully compatible with underlying HDF. This driver can import HDF4-EOS files. Currently EOS use HDF4-EOS for data storing (telemetry from "Terra" and "Aqua" satellites). In the future they will switch to HDF5-EOS format, which will be used for telemetry from "Aura" satellite.

6.60.1 Driver capabilities

Supports CreateCopy()

This driver supports the *GDALDriver::CreateCopy()* operation

Supports Create()

This driver supports the *GDALDriver::Create()* operation

Supports Georeferencing

This driver supports georeferencing

6.60.2 Multiple Image Handling (Subdatasets)

Hierarchical Data Format is a container for several different datasets. For data storing Scientific Datasets (SDS) used most often. SDS is a multidimensional array filled by data. One HDF file may contain several different SDS arrays. They may differ in size, number of dimensions and may represent data for different regions.

If the file contains only one SDS that appears to be an image, it may be accessed normally, but if it contains multiple images it may be necessary to import the file via a two step process. The first step is to get a report of the components images (SDS arrays) in the file using **gdalinfo**, and then to import the desired images using gdal_translate. The **gdalinfo** utility lists all multidimensional subdatasets from the input HDF file. The name of individual images (subdatasets) are assigned to the **SUBDATASET_n_NAME** metadata item. The description for each image is found in the **SUBDATASET_n_DESC** metadata item. For HDF4 images the subdataset names will be formatted like this:

HDF4_SDS:subdataset_type:file_name:subdataset_index

where *subdataset_type* shows predefined names for some of the well known HDF datasets, *file_name* is the name of the input file, and *subdataset_index* is the index of the image to use (for internal use in GDAL).

On the second step you should provide this name for **gdalinfo** or **gdal_translate** for actual reading of the data.

For example, we want to read data from the MODIS Level 1B dataset:

```
$ gdalinfo GSUB1.A2001124.0855.003.200219309451.hdf
Driver: HDF4/Hierarchical Data Format Release 4
Size is 512, 512
Coordinate System is `'
Metadata:
  HDFEOSVersion=HDFEOS_V2.7
  Number of Scans=204
  Number of Day mode scans=204
  Number of Night mode scans=0
  Incomplete Scans=0
```

...a lot of metadata output skipped...

```
Subdatasets:
  SUBDATASET_1_NAME=HDF4_SDS:MODIS_L1B:GSUB1.A2001124.0855.003.200219309451.hdf:0
  SUBDATASET_1_DESC=[408x271] Latitude (32-bit floating-point)
```

(continues on next page)

(continued from previous page)

```
  SUBDATASET_2_NAME=HDF4_SDS:MODIS_L1B:GSUB1.A2001124.0855.003.200219309451.hdf:1
  SUBDATASET_2_DESC=[408x271] Longitude (32-bit floating-point)
  SUBDATASET_3_NAME=HDF4_SDS:MODIS_L1B:GSUB1.A2001124.0855.003.200219309451.hdf:2
  SUBDATASET_3_DESC=[12x2040x1354] EV_1KM_RefSB (16-bit unsigned integer)
  SUBDATASET_4_NAME=HDF4_SDS:MODIS_L1B:GSUB1.A2001124.0855.003.200219309451.hdf:3
  SUBDATASET_4_DESC=[12x2040x1354] EV_1KM_RefSB_Uncert_Indexes (8-bit unsigned integer)
  SUBDATASET_5_NAME=HDF4_SDS:MODIS_L1B:GSUB1.A2001124.0855.003.200219309451.hdf:4
  SUBDATASET_5_DESC=[408x271] Height (16-bit integer)
  SUBDATASET_6_NAME=HDF4_SDS:MODIS_L1B:GSUB1.A2001124.0855.003.200219309451.hdf:5
  SUBDATASET_6_DESC=[408x271] SensorZenith (16-bit integer)
  SUBDATASET_7_NAME=HDF4_SDS:MODIS_L1B:GSUB1.A2001124.0855.003.200219309451.hdf:6
  SUBDATASET_7_DESC=[408x271] SensorAzimuth (16-bit integer)
  SUBDATASET_8_NAME=HDF4_SDS:MODIS_L1B:GSUB1.A2001124.0855.003.200219309451.hdf:7
  SUBDATASET_8_DESC=[408x271] Range (16-bit unsigned integer)
  SUBDATASET_9_NAME=HDF4_SDS:MODIS_L1B:GSUB1.A2001124.0855.003.200219309451.hdf:8
  SUBDATASET_9_DESC=[408x271] SolarZenith (16-bit integer)
  SUBDATASET_10_NAME=HDF4_SDS:MODIS_L1B:GSUB1.A2001124.0855.003.200219309451.hdf:9
  SUBDATASET_10_DESC=[408x271] SolarAzimuth (16-bit integer)
  SUBDATASET_11_NAME=HDF4_SDS:MODIS_L1B:GSUB1.A2001124.0855.003.200219309451.hdf:10
  SUBDATASET_11_DESC=[408x271] gflags (8-bit unsigned integer)
  SUBDATASET_12_NAME=HDF4_SDS:MODIS_L1B:GSUB1.A2001124.0855.003.200219309451.hdf:12
  SUBDATASET_12_DESC=[16x10] Noise in Thermal Detectors (8-bit unsigned integer)
  SUBDATASET_13_NAME=HDF4_SDS:MODIS_L1B:GSUB1.A2001124.0855.003.200219309451.hdf:13
  SUBDATASET_13_DESC=[16x10] Change in relative responses of thermal detectors (8-bit␣
↪unsigned integer)
  SUBDATASET_14_NAME=HDF4_SDS:MODIS_L1B:GSUB1.A2001124.0855.003.200219309451.hdf:14
  SUBDATASET_14_DESC=[204x16x10] DC Restore Change for Thermal Bands (8-bit integer)
  SUBDATASET_15_NAME=HDF4_SDS:MODIS_L1B:GSUB1.A2001124.0855.003.200219309451.hdf:15
  SUBDATASET_15_DESC=[204x2x40] DC Restore Change for Reflective 250m Bands (8-bit␣
↪integer)
  SUBDATASET_16_NAME=HDF4_SDS:MODIS_L1B:GSUB1.A2001124.0855.003.200219309451.hdf:16
  SUBDATASET_16_DESC=[204x5x20] DC Restore Change for Reflective 500m Bands (8-bit␣
↪integer)
  SUBDATASET_17_NAME=HDF4_SDS:MODIS_L1B:GSUB1.A2001124.0855.003.200219309451.hdf:17
  SUBDATASET_17_DESC=[204x15x10] DC Restore Change for Reflective 1km Bands (8-bit␣
↪integer)
Corner Coordinates:
Upper Left  (    0.0,    0.0)
Lower Left  (    0.0,  512.0)
Upper Right (  512.0,    0.0)
Lower Right (  512.0,  512.0)
Center      (  256.0,  256.0)
```

Now select one of the subdatasets, described as `[12x2040x1354] EV_1KM_RefSB (16-bit unsigned integer)`:

```
$ gdalinfo HDF4_SDS:MODIS_L1B:GSUB1.A2001124.0855.003.200219309451.hdf:2
Driver: HDF4Image/HDF4 Internal Dataset
Size is 1354, 2040
Coordinate System is `'
Metadata:
  long_name=Earth View 1KM Reflective Solar Bands Scaled Integers
```

...metadata skipped...

```
Corner Coordinates:
Upper Left  (    0.0,    0.0)
Lower Left  (    0.0, 2040.0)
Upper Right ( 1354.0,    0.0)
Lower Right ( 1354.0, 2040.0)
Center      (  677.0, 1020.0)
Band 1 Block=1354x2040 Type=UInt16, ColorInterp=Undefined
Band 2 Block=1354x2040 Type=UInt16, ColorInterp=Undefined
Band 3 Block=1354x2040 Type=UInt16, ColorInterp=Undefined
Band 4 Block=1354x2040 Type=UInt16, ColorInterp=Undefined
Band 5 Block=1354x2040 Type=UInt16, ColorInterp=Undefined
Band 6 Block=1354x2040 Type=UInt16, ColorInterp=Undefined
Band 7 Block=1354x2040 Type=UInt16, ColorInterp=Undefined
Band 8 Block=1354x2040 Type=UInt16, ColorInterp=Undefined
Band 9 Block=1354x2040 Type=UInt16, ColorInterp=Undefined
Band 10 Block=1354x2040 Type=UInt16, ColorInterp=Undefined
Band 11 Block=1354x2040 Type=UInt16, ColorInterp=Undefined
Band 12 Block=1354x2040 Type=UInt16, ColorInterp=Undefined
```

Or you may use **gdal_translate** for reading image bands from this dataset.

Note that you should provide exactly the contents of the line marked **SUBDATASET_n_NAME** to GDAL, including the **HDF4_SDS:** prefix.

This driver is intended only for importing remote sensing and geospatial datasets in form of raster images. If you want explore all data contained in HDF file you should use another tools (you can find information about different HDF tools using links at end of this page).

6.60.3 Georeference

There is no universal way of storing georeferencing in HDF files. However, some product types have mechanisms for saving georeferencing, and some of these are supported by GDAL. Currently supported are (*subdataset_type* shown in parenthesis):

- HDF4 files created by GDAL (**GDAL_HDF4**)
- ASTER Level 1A (**ASTER_L1A**)
- ASTER Level 1B (**ASTER_L1B**)
- ASTER Level 2 (**ASTER_L2**)
- ASTER DEM (**AST14DEM**)
- MODIS Level 1B Earth View products (**MODIS_L1B**)
- MODIS Level 3 products (**MODIS_L3**)
- SeaWiFS Level 3 Standard Mapped Image Products (**SEAWIFS_L3**)

By default the hdf4 driver only reads the gcps from every 10th row and column from EOS_SWATH datasets. You can change this behavior by setting the GEOL_AS_GCPS environment variable to PARTIAL (default), NONE, or FULL.

6.60.4 Creation Issues

This driver supports creation of the HDF4 Scientific Datasets. You may create set of 2D datasets (one per each input band) or single 3D dataset where the third dimension represents band numbers. All metadata and band descriptions from the input dataset are stored as HDF4 attributes. Projection information (if it exists) and affine transformation coefficients also stored in form of attributes. Files, created by GDAL have the special attribute:

"Signature=Created with GDAL (http://www.remotesensing.org/gdal/)"

and are automatically recognised when read, so the projection info and transformation matrix restored back.

Creation options can be specified in command-line tools using the syntax `-co <NAME>=<VALUE>` or by providing the appropriate arguments to *GDALCreate()* (C) or *Driver.Create* (Python). The following creation options are supported:

RANK=[2/3]: Defaults to 3. Create **n**-dimensional SDS. Currently only 2D and 3D datasets supported. By default a 3-dimensional dataset will be created.

6.60.5 Metadata

All HDF4 attributes are transparently translated as GDAL metadata. In the HDF file attributes may be assigned assigned to the whole file as well as to particular subdatasets.

6.60.6 Open options

Open options can be specified in command-line tools using the syntax `-oo <NAME>=<VALUE>` or by providing the appropriate arguments to *GDALOpenEx()* (C) or *gdal.OpenEx* (Python). The following open option is supported:

LIST_SDS=[AUTO/YES/NO]: (GDAL >= 3.2) Whether to report Scientific Data Sets (SDS). By default, when a HDF file contains EOS_SWATH or EOS_GRID, SDS will not be listed as GDAL subdatasets (as this would cause them to be reported twice). Listing them can be forced by setting LIST_SDS to YES.

6.60.7 Multidimensional API support

Added in version 3.1.

The HDF4 driver supports the *Multidimensional Raster Data Model* for reading operations.

6.60.8 Driver building

This driver built on top of NCSA HDF library, so you need one to compile GDAL with HDF4 support. You may search your operating system distribution for the precompiled binaries or download source code or binaries from the NCSA HDF Home Page (see links below).

Please note, that NCSA HDF library compiled with several defaults which is defined in *hlimits.h* file. For example, *hlimits.h* defines the maximum number of opened files:

```
#   define MAX_FILE   32
```

If you need open more HDF4 files simultaneously you should change this value and rebuild HDF4 library (and relink GDAL if using static HDF libraries).

6.61 HDF5 -- Hierarchical Data Format Release 5 (HDF5)

Driver short name

HDF5

Driver short name

HDF5Image

Build dependencies

libhdf5

This driver intended for HDF5 file formats importing.

Starting with GDAL 3.7, the driver can parse HDF-EOS5 encoded grid and swath metadata to establish projection and geotransform (for grids), and geolocation array (for swaths)

6.61.1 Driver capabilities

Supports Georeferencing

This driver supports georeferencing

Supports VirtualIO

This driver supports *virtual I/O operations (/vsimem/, etc.)*

6.61.2 Multiple Image Handling (Subdatasets)

Hierarchical Data Format is a container for several different datasets. For data storing. HDF contains multidimensional arrays filled by data. One HDF file may contain several arrays. They may differ in size, number of dimensions.

The first step is to get a report of the components images (arrays) in the file using **gdalinfo**, and then to import the desired images using gdal_translate. The **gdalinfo** utility lists all multidimensional subdatasets from the input HDF file. The name of individual images (subdatasets) are assigned to the **SUBDATASET_n_NAME** metadata item. The description for each image is found in the **SUBDATASET_n_DESC** metadata item. For HDF5 images the subdataset names will be formatted like this:

HDF5:file_name:subdataset

where:
file_name is the name of the input file, and
subdataset is the dataset name of the array to use (for internal use in GDAL).

Starting with GDAL 3.10, specifying the `-if HDF5` option to command line utilities accepting it, or `HDF5` as the only value of the `papszAllowedDrivers` of *GDALOpenEx()*, also forces the driver to recognize the passed filename, when it is not using subdataset syntax (it can typically be used to force open a netCDF file that would be nominally recognized by the netCDF driver).

On the second step you should provide this name for **gdalinfo** or **gdal_translate** for actual reading of the data.

For example, we want to read data from the OMI/Aura Ozone (O3) dataset:

```
$ gdalinfo OMI-Aura_L2-OMTO3_2005m0326t2307-o03709_v002-2005m0428t201311.he5
Driver: HDF5/Hierarchical Data Format Release 5
Size is 512, 512
Coordinate System is `'

Subdatasets:
  SUBDATASET_1_NAME=HDF5:"OMI-Aura_L2-OMTO3_2005m0113t0224-o02648_v002-2005m0625t035355.

You may use **gdal_translate** for reading image bands from this dataset.

Note that you should provide exactly the contents of the line marked **SUBDATASET_n_NAME** to GDAL, including the **HDF5:** prefix.

This driver is intended only for importing remote sensing and geospatial datasets in form of raster images(2D or 3D arrays). If you want explore all data contained in HDF file you should use another tools (you can find information about different HDF tools using links at end of this page).

6.61.3 Georeference

There is no universal way of storing georeferencing in HDF files. However, some product types have mechanisms for saving georeferencing, and some of these are supported by GDAL. Currently supported are (*subdataset_type* shown in parenthesis):

- HDF5 OMI/Aura Ozone (O3) Total Column 1-Orbit L2 Swath 13x24km (**Level-2 OMTO3**)
- HDF-EOS5 grids (starting with GDAL 3.7)
- HDF-EOS5 swaths (starting with GDAL 3.7)

6.61.4 Multi-file support

Starting with GDAL 3.1, the driver supports opening datasets split over several files using the 'family' HDF5 file driver. For that, GDAL must be provided with the filename of the first part, containing in it a single '0' (zero) character, or ending with 0.h5 or 0.hdf5

6.61.5 Multidimensional API support

Added in version 3.1.

The HDF5 driver supports the *Multidimensional Raster Data Model* for reading operations.

6.61.6 Driver building

This driver built on top of NCSA HDF5 library, so you need to download prebuild HDF5 libraries: HDF5-1.6.4 library or higher. You also need zlib 1.2 and szlib 2.0. For windows user be sure to set the attributes writable (especially if you are using Cygwin) and that the DLLs can be located somewhere by your PATH environment variable. You may also download source code NCSA HDF Home Page (see links below).

6.61.7 See Also

Implemented as hdf5dataset.cpp and hdf5imagedataset.cpp.

The NCSA HDF5 Download Page at the National Center for Supercomputing Applications

The HDFView is a visual tool for browsing and editing NCSA HDF4 and HDF5 files.

Documentation to individual products, supported by this driver:

- OMTO3: OMI/Aura Ozone (O3) Total Column 1-Orbit L2 Swath 13x24km V003
- HDF-EOS5 Data Model, File Format and Library

6.62 HEIF / HEIC -- ISO/IEC 23008-12 High Efficiency Image File Format

Added in version 3.2.

Driver short name

HEIF

Build dependencies

libheif (>= 1.1), built against libde265

High Efficiency Image File Format (HEIF) is a container format for individual images and image sequences. The driver has mostly been developed and tested to be able to read images using the High Efficiency Video Coding (HEVC, ITU-T H.265) codec. Such images are usually called HEIC (HEVC in HEIF) files, and have the .heic extension. iOS 11 can generate such files.

libheif 1.4 or later is needed to support images with more than 8-bits per channel.

Later versions of libheif may also support one or more of AVIF (AV1 in HEIF), JPEG, JPEG 2000 and uncompressed images depending on compile-time options.

The driver can read EXIF metadata (exposed in the `EXIF` metadata domain) and XMP metadata (exposed in the `xml:XMP` metadata domain)

The driver will expose the thumbnail as an overview (when its number of bands matches the number of bands in the full resolution image).

If a file contains several top-level images, they will be exposed as GDAL subdatasets.

6.62.1 AVIF support

Starting with GDAL 3.10, the AVIF_HEIF companion driver to the HEIF driver may be used to open images encoding with the AVIF (AV1 Image File) codec if the *AVIF -- AV1 Image File Format* driver is not available and if libheif has been compiled with support for one of the libraries it support that are able of AV1 decoding (libaom or libdav1d).

6.62.2 Driver capabilities

Supports VirtualIO

if libheif >= 1.4

Supports CreateCopy()

This driver supports the *`GDALDriver::CreateCopy()`* operation

Supports Georeferencing

This driver supports georeferencing

6.62.3 Georeferencing

HEIF provides experimental read-only support for GeoHEIF internal referencing, based on the draft OGC 24-038 design. There is no support for writing at this time.

This requires at least libheif 1.19.0.

6.62.4 Built hints on Windows

- Download source archives for libheif at https://github.com/strukturag/libheif and libde265 at https://github.com/strukturag/libde265
- Unpack the archives (for example libde265-1.0.5.tar.gz and libheif-1.7.0.tar.gz)
- Build libde265:

```
cd libde265-1.0.5
mkdir build
cd build
cmake -G "Visual Studio 15 2017 Win64" .. -DCMAKE_INSTALL_PREFIX=c:/dev/
↪install-libheif
cmake --build . --config Release --target install
cd ..
copy libde265\de265.h c:/dev/install-libheif/include/libde265
```

(continues on next page)

(continued from previous page)

```
copy libde265\de265-version.h c:/dev/install-libheif/include/libde265
cd ..
```

- Build libheif with libde265 support:

```
cd libheif-1.7.0
mkdir build
cd build
cmake -G "Visual Studio 15 2017 Win64" .. \
    -DCMAKE_INSTALL_PREFIX=c:/dev/install-libheif \
    -DLIBDE265_FOUND=ON \
    -DLIBDE265_CFLAGS=/Ic:/dev/install-libheif/include \
    -DLIBDE265_LIBRARIES=c:/dev/install-libheif/lib/libde265
```

- Add in GDAL's nmake.local the following lines before building GDAL:

```
HEIF_INC = -Ic:\dev\install-libheif\include
HEIF_LIB = C:\dev\install-libheif\lib\heif.lib
```

6.63 HF2 -- HF2/HFZ heightfield raster

Driver short name

HF2

Driver built-in by default

This driver is built-in by default

GDAL supports reading and writing HF2/HFZ/HF2.GZ heightfield raster datasets.

HF2 is a heightfield format that records difference between consecutive cell values. HF2 files can also optionally be compressed by the gzip algorithm, and so the HF2.GZ files (or HFZ, equivalently) may be significantly smaller than the uncompressed data. The file format enables the user to have control on the desired accuracy through the vertical precision parameter.

GDAL can read and write georeferencing information through extended header blocks.

6.63.1 Driver capabilities

Supports CreateCopy()

This driver supports the *GDALDriver::CreateCopy()* operation

Supports Georeferencing

This driver supports georeferencing

Supports VirtualIO

This driver supports *virtual I/O operations (/vsimem/, etc.)*

6.63.2 Creation options

Creation options can be specified in command-line tools using the syntax `-co <NAME>=<VALUE>` or by providing the appropriate arguments to *`GDALCreate()`* (C) or *`Driver.Create`* (Python). The following creation options are supported:

- **COMPRESS=[YES/NO]:** Defaults to `NO`. Whether the file must be compressed with GZip.
- **BLOCKSIZE=value:** Defaults to `256`. Internal tile size. Must be >= 8.
- **VERTICAL_PRECISION=value:** Defaults to `0.01`. Vertical precision. Must be > 0. Increasing the vertical precision decreases the file size, especially with *`COMPRESS=YES`*, but at the loss of accuracy.

6.64 HFA -- Erdas Imagine .img

Driver short name

HFA

Driver built-in by default

This driver is built-in by default

GDAL supports Erdas Imagine .img format for read access and write. The driver supports reading overviews, palettes, and georeferencing. It supports the Erdas band types u8, s8, u16, s16, u32, s32, f32, f64, c64 and c128.

Compressed and missing tiles in Erdas files should be handled properly on read. Files between 2GiB and 4GiB in size should work on Windows NT, and may work on some Unix platforms. Files with external spill files (needed for datasets larger than 2GiB) are also supported for reading and writing.

Metadata reading and writing is supported at the dataset and band level. But this is GDAL specific metadata, not metadata in an Imagine recognized form. The metadata is stored in a table called GDAL_MetaData which as many columns as metadata items. The title of the column is the `key` of the `key``=``value` metadata item pair and the value of row 1 is `value`.

6.64.1 Driver capabilities

Supports CreateCopy()

This driver supports the *`GDALDriver::CreateCopy()`* operation

Supports Create()

This driver supports the *GDALDriver::Create()* operation

Supports Georeferencing

This driver supports georeferencing

Supports VirtualIO

This driver supports *virtual I/O operations (/vsimem/, etc.)*

6.64.2 Creation Issues

Erdas Imagine files can be created with any GDAL defined band type, including the complex types. Created files may have any number of bands. Pseudo-Color tables will be written if using the GDALDriver::CreateCopy() methodology. Most projections should be supported, though translation of unusual datums (other than WGS84, WGS72, NAD83, and NAD27) may be problematic.

Creation options can be specified in command-line tools using the syntax `-co <NAME>=<VALUE>` or by providing the appropriate arguments to *GDALCreate()* (C) or *Driver.Create* (Python). The following creation options are supported:

- **BLOCKSIZE=32-2048:** Defaults to `64`. Tile width/height.
- **USE_SPILL=[YES/NO]:** Defaults to `NO`. Force the generation of a spill file (by default spill file created for images larger 2GiB only).
- **COMPRESSED=[YES/NO]:** Defaults to `NO`. Create file as compressed. Use of spill file disables compression.
- **NBITS=[1/2/4]:** Create file with special sub-byte data types.
- **PIXELTYPE=[DEFAULT/SIGNEDBYTE]:** By setting this to SIGNEDBYTE, a new Byte file can be forced to be written as signed byte. Starting with GDAL 3.7, this option is deprecated and Int8 should rather be used.
- **AUX=[YES/NO]:** Defaults to `NO`. To create a .aux file.
- **IGNOREUTM=[YES/NO]:** Defaults to `NO`. Ignore UTM when selecting coordinate system - will use Transverse Mercator. Only used for Create() method.
- **STATISTICS=[YES/NO]:** Defaults to `NO`. To generate statistics and a histogram.
- **DEPENDENT_FILE=<filename>:** Name of dependent file (must not have absolute path). Optional
- **FORCETOPESTRING=[YES/NO]:** Defaults to `NO`. Force the use of ESRI Projection Engine (PE) String in file instead of Imagine coordinate system format. In some cases this improves ArcGIS coordinate system compatibility.
- **DISABLEPESTRING=[YES/NO]:** (GDAL >= 3.7) Defaults to `NO`. Disable use of ESRI Projection Engine (PE) String in file. The default value is NO, allowing the ESRI PE String to be written if needed.

Erdas Imagine supports external creation of overviews (with gdaladdo for instance). To force them to be created in an .rrd file (rather than inside the original .img) set the global config option HFA_USE_RRD=YES).

Layer names can be set and retrieved with the GDALSetDescription/GDALGetDescription calls on the Raster Band objects.

Some HFA band metadata exported to GDAL metadata:

- LAYER_TYPE - layer type (athematic, ...)
- OVERVIEWS_ALGORITHM - layer overviews algorithm ('IMAGINE 2X2 Resampling', 'IMAGINE 4X4 Resampling', and others)

6.64.3 Configuration Options

Configuration options can be specified in command-line tools using the syntax `--config <NAME>=<VALUE>` or using functions such as *`CPLSetConfigOption()`* (C) or *`gdal.config_options`* (Python). Currently the following configuration options are supported by the HFA driver:

- **HFA_USE_RRD=[YES/NO]:** Whether to force creation of external overviews in Erdas rrd format and with .rrd file name extension (gdaladdo with combination -ro --config USE_RRD YES creates overview file with .aux extension).
- **HFA_COMPRESS_OVR=[YES/NO]:** Whether to create compressed overviews. Default is to only create compressed overviews when the file is compressed. This configuration option can be used when building external overviews for a base image that is not in Erdas Imagine format. Resulting overview file will use the rrd structure and have .aux extension.

  ```
  gdaladdo out.tif --config USE_RRD YES --config HFA_COMPRESS_OVR YES 2 4 8
  ```

  Erdas Imagine and older ArcGIS versions may recognize overviews for some image formats only if they have .rrd extension. In this case use:

  ```
  gdaladdo out.tif --config USE_RRD YES --config HFA_USE_RRD YES --config HFA_
  ↪COMPRESS_OVR YES 2 4 8
  ```

- **GDAL_HFA_OVR_BLOCKSIZE=value:** Defaults to `64`. The block size (tile width/height) used for overviews can be specified by setting this configuration option to a power-of-two value between 32 and 2048.
- **USE_SPILL=[YES/NO]:** Defaults to `NO`. Whether to use a spill file when creating a new overview.

6.65 RST -- Idrisi Raster Format

Driver short name

RST

Driver built-in by default

This driver is built-in by default

This format is basically a raw one. There is just one band per files, except in the RGB24 data type where the Red, Green and Blue bands are store interleaved by pixels in the order Blue, Green and Red. The others data type are unsigned 8

bits integer with values from 0 to 255 or signed 16 bits integer with values from -32.768 to 32.767 or 32 bits single precision floating point.32 bits. The description of the file is stored in a accompanying text file, extension RDC.

The RDC image description file doesn't include color table, or detailed geographic referencing information. The color table if present can be obtained by another accompanying file using the same base name as the RST file and SMP as extension.

For geographical referencing identification, the RDC file contains information that points to a file that holds the geographic reference details. Those files uses extension REF and resides in the same folder as the RST image or more likely in the Idrisi installation folders.

Therefore the presence or absence of the Idrisi software in the running operation system will determine the way that this driver will work. By setting the environment variable IDRISIDIR pointing to the Idrisi main installation folder will enable GDAL to find more detailed information about geographical reference and projection in the REF files.

Note that the RST driver recognizes the name convention used in Idrisi for UTM and State Plane geographic reference so it doesn't need to access the REF files. That is the case for RDC file that specify "utm-30n" or "spc87ma1" in the "ref. system" field. Note that exporting to RST in any other geographical reference system will generate a suggested REF content in the comment section of the RDC file.

- ".rst" the raw image file
- ".rdc" the description file
- ".smp" the color table file
- ".ref" the geographical reference file

6.65.1 Driver capabilities

Supports CreateCopy()

This driver supports the *GDALDriver::CreateCopy()* operation

Supports Create()

This driver supports the *GDALDriver::Create()* operation

Supports Georeferencing

This driver supports georeferencing

Supports VirtualIO

This driver supports *virtual I/O operations (/vsimem/, etc.)*

6.66 ILWIS -- Raster Map

Driver short name

ILWIS

Driver built-in by default

This driver is built-in by default

This driver implements reading and writing of ILWIS raster maps and map lists. Select the raster files with `the.mpr` (for raster map) or `the.mpl` (for maplist) extensions.

Features:

- Support for Byte, Int16, Int32 and Float64 pixel data types.
- Supports map lists with an associated set of ILWIS raster maps.
- Read and write geo-reference (.grf). Support for geo-referencing transform is limited to north-oriented GeoRef-Corner only. If possible the affine transform is computed from the corner coordinates.
- Read and write coordinate files (.csy). Support is limited to: Projection type of Projection and Lat/Lon type that are defined in .csy file, the rest of pre-defined projection types are ignored.

Limitations:

- Map lists with internal raster map storage (such as produced through Import General Raster) are not supported.
- ILWIS domain (.dom) and representation (.rpr) files are currently ignored.

NOTE: Implemented in ilwis.

6.67 IRIS -- Vaisala's weather radar software format

Driver short name

IRIS

Driver built-in by default

This driver is built-in by default

This read-only GDAL driver is designed to provide access to the products generated by the IRIS weather radar software.

IRIS software format includes a lot of products, and some of them aren't even raster. The driver can read currently:
